ORIGINAL ARTICLES

GUAIACOL IN THE TREATMENT OF TYPHOID FEVER IN CHILDREN

Read in the Section on Diseases of Children at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md, May 7-10, 1895

BY ADOLPH KOENIG, M D
PITTSBURG, PA

The comparative rarity of typhoid fever in children is probably entirely due to the fact of infrequent exposure, and not to any lessened degree of susceptibility as compared with adults I believe that it can now be accepted as proved, that typhoid fever is essentially a water borne disease and that drinking water rather than foul air or direct communication is the medium of infection We thus have an explanation of the rare occurrence of the disease in very young infants and the increasing ratio of its occurrence in children as they gradually receive more solid food and drink more water

The pathologic lesions of typhoid fever in children are necessarily identical with those in adults, except that in children who have passed their very earliest period of life, and in whom the constructive metabolism is at its height, the necrotic process, which in the adult often goes on to perforation of the wall of the intestines is in them resisted more strongly, by reason of their greater reparative power In very young infants this does not hold good, for in them the constructive forces are not yet established to their fullest power and statistics seem to prove that perforation of the intestine, in this class of patients is as frequent as in adults The difficulty of making an absolute diagnosis of typhoid fever in sucklings is however, very great and it is not unlikely that typhoid fever in them is often mistaken for the common diarrheal diseases of infants

Considering the ordinary innocuousness of typhoid fever in children, the question of treatment resolves itself more into a general hygienic and dietetic supervision, than into drug administration When, however, we consider the etiology and pathologic lesions present in the intestinal canal, during the latter stage of this disease, certain forms of medication seem rational and demanded According to the modern bacteriologic investigations, typhoid fever is a self-limited disease which reaches its climax at about the tenth or twelfth day, after the development of the first symptoms, and the activity of the bacillus typhosus apparently ends about the middle of the third week The pathologic lesions, however, remain in the form of ulcers, of greater or less circumference and depth, in the intestinal canal, and the disease then practically resolves itself into a surgical one The question which then arises is how to prevent the infection of the intestinal lesions with septic germs The intestinal tract is the fertile habitat of germs always ready to attack its tissues under conditions of reduced vitality, and to prevent the growth and multiplication of such germs, to render the intestinal canal as uninhabitable as possible for them, is to my mind a rational, and in my experience an efficacious, treatment of typhoid fever To render the intestinal tract as aseptic as possible, it becomes necessary to do more than to administer antiseptics The first treatment a case of typhoid fever should receive is to clear the intestinal canal as much as possible of all foreign matter, and next, the administration of food should be so regulated as to restrict to the greatest possible extent all fermentative processes during the height of the disease, at which time the digestive functions and the absorption of nutritive material are very seriously interfered with, if not entirely arrested

The treatment of typhoid fever in children adopted by me can best be described under the following subdivisions

Initiatory Treatment —When a child is seen for the first time, though the symptoms present point strongly to typhoid fever, it is impossible to make a positive diagnosis, but it is nevertheless my custom to place them upon treatment appropriate for typhoid fever The first object to be aimed at is to clear out the bowels, and this is done by the administration of calomel well triturated with sugar, in doses of 1-20 to 1 10 of a grain, according to the age of the child every two or three hours All solid food is immediately withheld, water however, being given to the extent of the patient's desire

Regular Treatment —If after a few days the temperature assumes the typhoid fever curve, the patient is at once placed on the following treatment

℞ Guaiacolis f ʒ i
Glycerini f ʒ i
Alcoholis f ʒ ii
M Sig One to six drops in whisky and water every two hours, according to the age of the patient

This treatment is continued throughout the course of the disease, the dose of the guaiacol being increased or decreased according to the severity of the symptoms The whisky is given in small quantities In that form I believe it to conserve the tissues of the patient, to stimulate his vital functions and to generally improve his well-being The dose is allowed to range from one-fourth to one teaspoonful, according to age

When no desire for food is manifested, or where a decided aversion for it exists, only meat broth and barley-water is given Milk is allowed either pure or diluted one half with barley-water, if the condition of the digestive functions seems to warrant it As soon as the bowels have become thoroughly emptied the calomel is withheld, to be again resumed should the indications demand it This is the case, as a rule, during the later stage of the disease

Under this plan of treatment, intestinal antisepsis is furthered as is evidenced by the slight degree of tympanitis, absence of sordes on the teeth and especially by the character of the stools, which are much less frequent and are practically destitute of the very disagreeable odor that characterized the passages of patients before the introduction of treatment directed toward intestinal antisepsis.

High temperature is combated by cold sponging alone. No depressing antipyretics of any kind are used.

While I claim that the course of an attack is materially modified in ordinary cases, I do not claim guaiacol as a specific, for under its use during the last five years, (creasote being used part of the time, in place of guaiacol) I have lost two cases. Both of these died during the latter part of the third week, apparently of acute disorganization of the central nerve centers. The peculiar cause of death in connection with these two fatal cases remains to be explained. In each case a younger brother succumbed to the same disease, under different treatment, and under the care of other practitioners within a short period of time. The question naturally arises, was there not some peculiar absence of resisting power in the members of the families in which these cases occurred? The course of the disease in these fatal cases was not specially severe, but as already stated at some time during the latter part of the third week the nerve centers suddenly became involved and death resulted from asthenia.

No difficulty whatever has been experienced in the administration of the remedy, which is a feature of no little value in remedies for children.

ACUTE LACUNAR DIPHTHERIA OF THE TONSILS

Read in the Section on Diseases of Children, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY HENRY KOPLIK, M.D.
NEW YORK.

The writer has been induced to appear before your distinguished body to enlarge upon a theme previously brought to the notice of the profession, because he was convinced that the possible gravity of the apparently simple angina or lacunar tonsillitis was not yet generally accepted.

In a recent discussion upon the antitoxin treatment of diphtheria in the New York Academy of Medicine, one of the prominent speakers referring to bacteriologic diagnoses of diphtheria and especially those diagnoses which reveal the diphtheria not accompanied by membrane or parts of membrane in the throat, said that where the bacteriologic diagnosis of diphtheria, in the absence of clinical evidences, quarantines the house or separates a family from relatives and friends it is a sin against man. A further statement goes on to characterize the treatment of these mild cases in a diphtheria ward as a crime, etc. Another speaker while admitting that he would not give such patients who had no clinical evidences of diphtheria in their throats (membrane or parts of membrane) a clean bill of health, said it was difficult to know what to do with such cases. The terms "clinical diphtheria," "clinical evidences of diphtheria," were freely used and insisted upon as a diagnostic element in all cases where effective isolation is contemplated, at least so one would surmise from a perusal of the printed discussion.

The above is mentioned to show that there is still a wide gap between those who work purely clinical and those who combine the clinical with the findings of scientific research. In other words, we have not advanced a step since the time of the immortal Trousseau, in the diagnosis and prophylaxis of the dread disease, diphtheria, or we have no right to advance. No membrane, no diphtheria! This, to a certain number, is as true to-day as it was in the days of the great pupil of Bretonneau. The writer wishes here to point out the great danger which such a quasi-sentimental definition of diphtheria must needs carry with it. In 1891 the writer of this article, convinced that the gravity of a certain class of apparently simple anginas was not appreciated, undertook to investigate both from a clinical and bacteriologic standpoint all varieties of anginas in which there could scarcely be said to exist at the outset, at least, any clinical evidences *locally* of diphtheria. There was in these cases no form of typical membrane. No such systematic attempt had been undertaken, up to this time, to the writer's knowledge. The profession were told from time to time, that during epidemics of diphtheria, or even in the absence of epidemic influence, what seemed to be a simple lacunar tonsillitis might eventuate as a diphtheria. Trousseau in his lectures upon diphtheria cites forms of lacunar amygdalitis followed by paralyses. These paralyses were similar to those which followed in cases of membranous diphtheria. Trousseau hesitated to call these anginas "diphtheria," even though followed by paralyses. There was no membrane, and he preferred to think rather that paralysis could follow in rare instances a simple tonsillitis. His inability to supply the connecting link between the membranous and the non-membranous cases of diphtheria was the only thing which deterred this clinician from grouping the two classes of cases under one heading. We are certain that had the link been at hand at that time, his views would have been more distinctly radical than they were. He simply said that certain simple anginas might rarely be followed by paralyses.

In 1886 we find this question still a mooted one. Jacobi, of New York, and Fraenkel, of Berlin, both clinical leaders in their respective cities, differed widely in their views upon these cases, Fraenkel insisting that the ground taken by his clinical opponent, that diphtheria may run its course as a lacunar amygdalitis, was too sweeping. At this time also, no proof additional to that submitted by former writers was brought forward to prove the theses of which we are speaking. Every one argued from clinical deduction purely, and clinical deductions seemed to differ when grouped by different observers. After all had been said and done, every one hung to the doctrine of Friedreich, that lacunar amygdalitis was an infectious disease, but would go no further.

Henoch (edition 1893) in his classical hand-book upon diseases of children says in the article upon diphtheria: "I do not recognize the existence of a pharyngeal diphtheria in the form of a simple angina."

Escherich (1890, Henoch's *Festschrift*) while denying the existence of Loffler bacilli in the lacunar tonsillitis of young children, admits their existence in cases of catarrhal anginas of older children, in cases in which at no time has there been membrane or clinical evidences of diphtheria Escherich, in this article is guarded in his conclusions and reserves a decided classification for the opportunity given by a larger material than he had at his disposal

Gerhardt was at this time also very decided in his view that danger lurked in the atypical diphtheria He pointed out their capability of causing diphtheria in others

In my first article (1891 *New York Medical Journal*) upon atypical cases of diphtheria, the first series of cases which were studied bacteriologically were similar to those seen and described clinically by Trousseau, Gerhardt and Escherich, in which we find at the outset no typical membrane Indeed, during the whole course of the disease, no membrane appeared to the naked eye The cases were those of a child 4 years of age, having the symptoms and local manifestations of a simple catarrhal angina, but in whose throat large numbers of virulent Loffler bacilli were found This case was associated in the same family with another severe non membranous angina, in a sister aged 5 years, to whom I presumed the first had communicated the illness, and in this second case we had the same bacteriologic result as in the first case During the whole illness, neither of these cases manifested any membrane Fully a week after the first case had been taken ill, a baby 2½ years old in the same family became afflicted with fatal diphtheria, in which membrane and portions of membrane appeared in the throat, and which also involved the larynx It will be thus seen that here was an almost faultless group of cases observed daily, in which two had the typical "diphtheria *sine membrana*," followed by a third case in the same family of true clinical diphthetia It will naturally be asked, Was diphtheria suspected in the catarrhal cases? Working upon diphtheria at the time, scrapings were obtained from these throats, as shown in my paper, and fortunately several times, and tested upon animals, the results justified our early suspicions The symptoms in these cases in which absolutely no membrane or points of membranous deposit appears in the throat, I must say are equivocal I have examined the throats of children who gave a set of clinical symptoms almost identical to the first class of cases and, as my work shows, I failed with equal precautions to find diphtheria bacilli Thus the croupy coughs, the red throats, fever, enlarged glands and, I may say, even prostration upon which the stress was formerly laid, are not characteristic The only way, it seems to the writer, to positively differentiate these cases is the bacteriologic method

Another class of cases in which we must always be put upon our guard, are those in which a minute speck of membrane appears on the tonsil or uvula, looking like a drop of fibrinous secretion combined with a typical lacunar tonsillitis These cases may be truly diphtheritic Again, a third set of cases, showing pultaceous deposits of a stringy fibrinous character may prove to be non diphtheritic or *vice versa* A fourth set of cases are those in which the tonsil is the seat of a necrotic ulcerative process, with no distinct membranous formation In only one part of the tonsil do we find an excavation, the base of which is covered with specks of exudate Henoch has described such cases, and many still speak of these cases as ulcerative sore throat I have proved many of these cases to be distinctly true diphtheria In some, the children are scarcely ill enough in the eyes of the parents to require treatment It will be seen that there are forms of angina which are diphtheritic in their etiology, in which at no time are there manifestations of membrane, or such exudate as does appear is atypical

Feer has confirmed the writer's work in the first set of cases, and it must now be admitted as firmly established that diphtheria "sine membrana" exists, though it introduces an unfortunate complexity into the problem of clinical diphtheria

The most important class of atypical cases of diphtheria and perhaps the most common are those in which the appearances in the throat resemble in every detail the simple lacunar tonsillitis

In 1894 I published a second paper, in which a series of consecutive cases, all giving the typical clinical picture of lacunar tonsillitis, were examined with special reference as to their diphtheritic or non diphtheritic character This paper adhered closely to this set of cases because in the first paper the material had spread over such a diverse field that it was not possible to judge the actual frequency of any particular set of the cases cited In this series of lacunar tonsillitis, fully one third of thirty-nine cases were shown to be true diphtheria It was possible here, also, to divide the cases into groups as far as the severity and clinical symptoms were concerned

The first group of cases are exceedingly mild, the patients show but little constitutional disturbance and complained but slightly of throat symptoms Examination shows general hyperemia of the fauces, enlarged tonsils with open lacunæ Some of the lacunæ showed an accumulation of yellow secretion at the surface opening The lymph nodes at the angle of the jaw may or may not be enlarged

The second group of lacunar diphtherias are those in which the local and constitutional symptoms are more pronounced The patients show more prostration, the fever is quite high and there are other symptoms as pains in the limbs, furred tongue, etc The tonsils are much enlarged and there exudes from the lacunæ a soft fibrinous exudate There is no form of membrane anywhere on the tonsil and the lymph nodes are much enlarged The plugs of these as also those of the first group contain Loffler bacilli

The third group of cases are those which show distinctly malignant features from the outset They do not remain purely lacunar after the first few days, and in this respect would resemble much, cases described by Heubner of membranous diphtheria, which early in their course resemble lacunar tonsillitis, and subsequently show coagulated exudate on the surface of the tonsil The cases described by the writer belonging to this group, are truly septic in character, and beginning with a picture of lacunar tonsillitis, the infants the first day, even before the membrane is seen, have pallor and prostration which is quite characteristic and may at once put us on our guard These are the cases which subsequently draw the nasal fossæ into the clinical picture They are also the fatal cases They begin as a lacunar tonsillitis and within forty-eight hours membrane and shreds of membrane are voided from behind the immensely swollen tonsils which completely occlude the fauces It is not the intention of the writer to rehearse here the details of the bacteriologic examination of these cases of lacunar diphtheria of the tonsils but there are some points which must be of vast and far reaching importance, and which have been established by the writer and since confirmed by Flexner, Booker (Johns Hopkins Bulletin, March, 1895), and others. The Löffler bacilli of diphtheria, in the cases of lacunar diphtheria are found, not so much on the surface of the tonsil, but in the depths of the lacunæ, in the fibrinous plugs, which occlude the lumina of the lacunæ. The bacilli are of equal virulence, whether obtained from the first group of mild cases or the third group of fatal septic lacunar diphtherias. The bacilli retain their virulence for weeks in the depths of the lacunæ, the patient being in apparent full convalescence, or the tonsils having returned to almost the normal size and appearance. In one case virulent bacilli were obtained from a lacunar plug of the tonsil in the third week of convalescence. A lacunar plug in one case, in which virulent bacilli had been isolated early in the disease showed non-virulent bacilli fully three weeks after the outset of the disease. In other words, virulent bacilli were replaced by the non-virulent variety in this particular lacunar amygdalitis.

Enough has been cited above, of the bacteriology of these cases, to show the importance of this class of cases of diphtheria. Too much weight can not be attached to these facts. We must not be turned aside by any fallacious arguments which continue to harp upon the desirability of a membrane in order to entitle a case to the dignity of the term, *clinical diphtheria*. This term, I believe, was first introduced into medicine by Trousseau. It is a landmark in the history of modern medicine, but it is time to protest against its use as a weapon with which to cast contempt on the class of cases concerned in this paper.

If prophylaxis is the ideal of modern hygiene, then the class of cases treated of in this paper, take a rank first in importance. Innocent in appearance, they are the means of disseminating a dread affection. Serious and unremitting isolation is the only method by which we can show our appreciation of their serious nature. Their importance crops out in the operating room constantly. At the last meeting of the American Pediatric Society, the writer of this paper insisted that those cases of tonsillotomy upon enlarged tonsils which were followed by membranous diphtheria, or even croup, were undoubtedly of the nature of the cases described in this paper. It has been shown by the writer that in these large tonsils, virulent diphtheria bacilli exist long into convalescence. As long as they are left to the natural fluids in the lacunæ no harm results to the patient, and we have even reason to believe, as pointed out in my second paper, that they gradually lose their original virulence. Cut this out, however, and you expose to the propagation of the bacilli in the lacunæ the most favored of growing media, a freshly cut surface bathed in lymph, and a membrane results, in some cases spreading to the fauces and larynx. One case of this kind is enough to convince the most skeptical, and yet there are many such, doubtless, who are waiting for the case to occur to them.

Diagnosis.—How can we approach the diagnosis of these cases? The old methods, such as proposed by Henoch, only apply to cases which finally develop membrane or portions of membrane. If we wish, however, to pick out the pure lacunar diphtherias in which membrane never forms, we will find that our safest method is the bacteriologic test. To test the urine to wait for specks of membrane to appear, only delays matters and does not aid us, for we have not only albuminuria in the streptococcus tonsillitis, but also glandular swellings and prostration with low and high curves of temperature. The opponents of bacteriologic diagnosis say that the Löffler bacillus has been found on the normal mucous membrane. Would you call such a case diphtheria and isolate it? The answer to this fallacious argument is plain. The well authenticated cases in which investigators of acknowledged rank (Löffler, Roux) have found virulent bacilli on the normal mucous membrane, are exceedingly rare and exceptional. They are found in throats perhaps exposed to a diphtheria atmosphere. Since the inauguration of the simple crude methods of diagnosing a case of diphtheria by growing a culture and staining a few covers has come more and more into vogue, the bacilli in the normal throats have multiplied in frequency. We would ask that methods showing such evident flaws be not taken too seriously. They are necessary in rapid hygienic work, but must not be brought forward as an argument.

Given an angina in which Löffler bacilli have been demonstrated to exist in large numbers, such a throat is diphtheritic and must be grouped with diphtheria, membranous or otherwise. It should be unmercifully isolated whether it isolates the patient from friends and family or sends the patient into a contagious ward where severe cases of diphtheria are treated. It has been maintained that the placing of such cases among severer cases is an injustice to the patient. Those who have studied diphtheria since the discovery of Löffler must subscribe to the views brought forward by Escherich. These mild cases of diphtheria must be explained on the ground of immunity. They do not develop membrane and can not develop severe diphtheria, because in these particular individuals there is a natural or acquired immunity which protects them against the severer manifestations of the disease. If you place them, therefore, in a ward in which there are very severe cases of diphtheria, no more injustice is done to the mild case of diphtheria than would be done to a correspondingly mild case of measles placed in a ward with very severe and complicated measles.

On the other hand, these mild cases of diphtheria or lacunar diphtheria or diphtheria "sine membrana" are capable of communicating fatal or severe diphtheria to others. If we grant the above, which is the result of years of work at the bedside and in the laboratory, the principal arguments of the alarmists fall to the ground.

CLINICAL EXPERIENCE WITH ANTITOXIN IN PRIVATE AND HOSPITAL PRACTICE IN THE TREATMENT OF DIPHTHERIA—(ALL FORMS).

Read in the Section on Diseases of Children at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY LOUIS FISCHER, M.D.

Instructor in Diseases of Children at the New York Post-graduate Medical School and Hospital, Physician in Charge of the Messiah Home, Physician to the Children's Department of the German Polyklinik.

NEW YORK.

My first successful case with antitoxin was published in the *New York Medical Record*, Oct. 6, 1894, in which a child 11 years old was attended by Dr. Gerlach. In this case I injected 5 ccm. of Aronson's antitoxin between the shoulder blades. The child was discharged, cured, on the fourth day. This patient was presented before the New York Post Graduate Clinical Society at its first meeting in the Hospital Building in October

Since then I have published a series of papers, embodying various clinical experiences, notably, however, papers that appeared on Nov 17, 1894, in the *New York Medical Record* A series of thirty six cases which were attended by me, was published in the January number of the *American Journal of Medical Science*, wherein I reported a very successful list of cases

My percentage of deaths was but 5 8 per cent The antitoxin used was brought over by me from Berlin last summer Some of my patients were attended in the Municipal Hospital, Philadelphia, through the extreme courtesy of Dr Welch, the supervising physician in charge, and also through Dr Edward Davis, the editor of the *American Journal of Medical Sciences* It is only necessary for me, however, to refer to the paper read by me before the German Medical Society of New York on March 4, 1895, in which I reported a series of 223 cases These were largely made up of cases attended in hospitals and private practice, but most of them were those seen in consultation The paper has since then appeared *in extenso* in the *New York Medical Record*, April 6 1895 The mortality among the 223 cases was 15 11 per cent This was by me in January, and can be accounted for in various more than twice as much as the first mortality, reported ways 1, a great many cases were seen in consultation and were cases which were moribund, in other words, hopeless cases, and cases in which antitoxin was used as a last resort, 2, a great many deaths were also in children that had been suffering from mixed infections, cases of scarlet fever and diphtheria, cases of chickenpox and diphtheria, cases of measles and diphtheria It is here that we can not look for any benefit from the antitoxin, because in some cases, especially in those which were fatal, I found that I was rather called upon to treat cases of septicemia and not cases of toxism, caused only by one infection, the Klebs-Loffler bacillus but rather the combined septic influences of the Klebs-Loffler bacillus and the streptococcus in scarlet fever and other microorganisms with which we are not so familiar

A very interesting case, and one which I published in detail, was a consultation case with Dr Roberts, of New York, wherein I refused to inject antitoxin, owing to a scarlet fever complication In this case we had both diphtheria and scarlet fever, and the child presented a typical appearance of sepsis The child died about one or two hours after I saw it, and if I had injected this case, we might have believed the antitoxin was again inert I had, however, injected a prophylactic dose of antitoxin in another child in the same family, in the presence of Dr Roberts This child had been exposed to diphtheria, remained immune and was well when I last heard from it through Dr Roberts, the attending physician

The constant differences in strength, presence of noxious albuminoidal bodies, and other drawbacks, have given rise to complaints of inefficacy, occurrence of secondary effects and sequelæ, and even deaths The use of such uncertain preparations tends to create confusion, and has already given rise to personal recriminations in the medical papers The investigations of Wernicke, Ehrlich, Behring and Aronson on the question of acquired immunity from diphtheria, which were published in the scientific journals, have enabled some manufacturers to produce a serum which is more apt to prejudice the value of the original discovery than to supply the demand for an efficient remedy

It may be pointed out here, that antitoxin is not made by merely inoculating an animal, drawing off the blood after a certain interval, coagulating and separating the serum Antitoxin and serum are not synonymous terms Aronson's antitoxin, with which the best results were obtained, and on which the first clinical reports have been based, is a highly concentrated antitoxin, from which the inert and noxious constituents of the serum are eliminated

The antitoxin made in Schering's bacteriologic department is, since April 1, controlled by the German government The official demands require that the serum is clear, containing at the most only a slight sediment, that the preservative is used in the proper proportions and that the antitoxin possesses the specified degree of immunizing power This control is carried out in the Berlin Institute for Infectious Diseases, the weighing out, the drawing of samples, and filling in the factory being conducted in the presence of a sworn State officer Further, the State requirements include the control of the health of the animals, the keeping of a control book, in which entries are made of all the horses, the period of their treatment, the amount and frequency of the blood-drawing, etc

Physicians will readily see the importance of this measure, giving a satisfactory guaranty that the preparation has been made, tested and put up under the direct supervision of the German government and independent scientific experts

Another important point in connection with the preparation is its keeping qualities Dr Aronson's antitoxin, which is preserved with four tenths of 1 per cent of trikresol, keeps for an unlimited period of time, and according to the latest investigations, retains its full efficacy for at least one year

In order to illustrate a few cases which have not been hitherto published and which are some of my most recent publication cases, permit me to offer the following

Katie K, child 4 years old, was brought to the office of Dr R H Theyson, on April 18, 1895, to be treated for vomiting Examination found the temperature 100, pulse 100 very slightly congested April 14, temperature remained 100 pulse 110, vomiting had ceased, congestion in the throat slightly increased The Doctor put the child on the ordinary form of antipyretic treatment and also prescribed an astringent for the throat April 15 the temperature was 103 pulse 120 and slight patches of dirty white membrane were visible on the left tonsil, a small patch on the uvula and the breath was fetid The child [illegible] arently in good health and lively On April 16, at 9 [illegible] the temperature was 103, pulse 140, the child very sl[illegible] an extremely rapid increase of the membrane, which was thick and tough, covering both tonsils, pharynx, uvula and there was an acrid discharge from both nares The breath was extremely vile This case was also seen on the same day by Dr Brackes I was called in consultation at 7 30 on the evening of April 16, with Dr Theyson, and found the throat completely covered with large masses of pseudo membranes Temperature 103, pulse 104 In order to corroborate the diagnosis, I made a culture on blood serum through the courtesy of the attending physician, which proved Klebs-Löffler bacilli, and I was also asked to inject antitoxin I injected 5 ccm of Aronson's antitoxin using the ordinary antiseptic precautions for the skin and instruments, between the interscapular region The morning after I injected the antitoxin the temperature was 103 the pulse 140 The child feels brighter and there seems to be no increase of the membrane Slight amount of albumin in the urine April 18, pulse 140 temperature 102 vomited some small pieces of membrane at 9 30 in the even ing Owing to a feeble pulse, free stimulants were ordered April 19, pulse 120, temperature 120 The child has vomited considerable pieces of membrane Two pieces were the size of 10 cent pieces The appearance of the membrane in the throat is somewhat thinner April 20, temperature 100, pulse 110, child very bright April 21, membrane has disappeared from both tonsils, seems to be very thin on the posterior nares, temperature 100, pulse 110 April 22, temperature 99, pulse 110 April 23, temperature 98 5, pulse 90 Membrane is gradually disappearing April 24, temperature 101, pulse 100, membrane almost gone, albumin still in the urine April 25, temperature 98, pulse 100, discharge from the nares stopped April 26, 27 and 28, temperature 99 and pulse 100 On April 26, membrane disappeared April 28, patient discharged cured

On April 16, the culture made by me proved Klebs-Loffler bacilli This is one of my typical cases, as I have seen them and as I have been used to treating them and, although it was agreed that this was a very bad case and that under ordinary circumstances we would give a very fatal prognosis, this child is well and received no other medication, excepting naso-pharyngeal irrigation and local applications of some antiseptic solution

A second case equally interesting is the following I was called on April 13, by Dr A W Newfield, to see a case of laryngeal stenosis and membranous diphtheria, involving the complete naso-pharynx, both tonsils and uvula The child was in such bad condition, that although I was called to inject antitoxin, I told the attending physician that it would very likely require intubation before evening This was about 3 P M That evening, Dr Emil Mayer was called in consultation to introduce a tube The following day, by appointment, I met Dr Newfield, Dr Emil Mayer and Dr N S Roberts On talking this case over, we decided that there till was severe laryngeal stenosis, and it was agreed that I hould be permitted to examine the case I was surprised o find no tube It was plain to me that the child had probably coughed up the tube and swallowed it I was permitted to intubate the child, which was rapidly done in the presence of the three physicians Breathing at once was easier and the stenosis relieved I did not hear from the case until Tuesday, when Dr A W Newfield, the attending physician, called on me to extubate, as the child was entirely well I begged the doctor to permit the tube to remain *in situ* for at least two days longer, on the following Thursday I removed the tube The child remained well

In this case the prognosis was so bad that it was considered a hopeless case and the attending physician believed, as well as I did, that the case was a bad one, but having seen worse cases get well, I decided to give only a cautious prognosis In this case the urine was examined by Dr Newfield and found normal, there evidently was no irritation caused by the antitoxin I injected only 5 ccm of Aronson's antitoxin between the shoulder blades and ordered naso-pharyngeal antisepsis, consisting of washing the nares and throat with a normal saline solution (warm)

The third case and still more interesting than the above two, was one that was referred to me by the kindness of Prof H J Boldt of this city on April 7 A child, about 2 years old, in extreme dyspnea, was seen by Professor Boldt and he wrote me that it was of the utmost importance to relieve the laryngeal stenosis by intubation I intubated and the relief was immediate I allowed the tube to remain three days and extubated, when the membranes reappeared and it was necessary to re intubate This has been done in all four times The depth of the disease and the malignancy of this case can only be imagined, when we consider that we have an extension of the disease from the pharynx to the larynx, and from the larynx to the trachea and as far down as we can not see but only conjecture Long shreds of membrane are to day coughed up, exactly as they were two weeks ago The temperature has been varying between 103 and 101

Owing to the great risk of feeding and causing pneumonia, in all my cases I have insisted from the first in feeding per rectum, by using an emulsion, consisting of the yolk of an egg and starch water, and beef tea mixed with starch water, and also injected stimulants in the same manner when indicated I have found that children can get along very well for a week without feeding through the mouth, nor do I give anything through the mouth to quench thirst, but rely solely upon these enemata for both thirst and nourishment

In all my cases it has been a surprising fact, the amount of good that could be done by combining intubation and antitoxin, but we must know that we are using antitoxin and a reliable preparation of the same only The condition of the glands, the condition of the pseudo membrane, the temperature curve, the pulse, the heart's action, the urine, the skin and the eruptions following injection of antitoxin are points on which I have already elaborated in the series of papers, which I have quoted in the beginning of this short paper and to which I would beg to refer I can not therefore take up your valuable time and go into detail on the above subjects without encroaching on the time usually allotted to a paper of this kind Suffice it to say, that the mortality of my cases of diphtheria, as compared with the mortality of my cases of diphtheria before the antitoxin era is at least 500 per cent better

When such eminent men as Professors Heubner, Baginsky, von Wiederhofer of Vienna, von Ranck of Munich, Rauchfuss of St Petersburg, von Mehring of Halle, Vierordt, von Norden, Seitz of Munich and others, will suddenly change all hitherto known therapeutics, and as at the Thirteenth Congress of Internal Medicine, which was held in Munich in April, 1895, suddenly drop all former medication and get enthusiastic over antitoxin and what it will do in diphtheria, then there must be some real reason for it When I was at Berlin, Professor Baginsky told me that the mortality of diphtheria had been during the last four or five years about 40 to 42 per cent, and suddenly during the introduction of antitoxin, the mortality went down to about 12 per cent Through some accident no antitoxin could be had for a short time and again the mortality rose to almost 50 per cent, and then when antitoxin was again to be had, went down to 10 per cent These facts, as they are the true statistics from one of the renowned hospitals in Berlin, the Emperor and Empress Frederick Children's Hospital, will speak volumes The same can be said about the sudden enthusiasm of Professor Heubner

There are a great many contra-indications to the use of antitoxin and these have been pointed out by me in an elaborate paper published in the *Medical Record* on April 6, 1895 Especially must we be careful where there has been a severe form of kidney trouble prior to the attack of diphtheria and especially so where there has been a great amount of irritation in the urine But do we not always use great caution when putting a patient under ether and inquire whether he has had kidney trouble formerly? We all recognize there are certain drugs that would irritate the kidneys, that would interfere with the usual heart's action, some like digitalis, that have a very irritable effect upon the stomach, again other drugs in which we must use great caution, owing to their injurious effect within the body If this be so, why should we not use great caution and judgment in prescribing antitoxin, and inquire if there are not some contra indications for its use, but with my experience to day, covering over 260 odd cases, we must believe that some of the brilliant results attained by me have been due and only due to antitoxin I will only refer to the case I have reported, in consultation with Dr Newfield and which was intubated in the presence of three colleagues The other case of Dr Theyson is equally illustrative I would not be willing to attend a case of diphtheria to day, with what I have learned and seen in hospital and private practice, without antitoxin, any more than I would be willing to attend and promise a good result in any form of intermittent fever without quinin, or promise any decent result with other drugs than mercury in syphilis

Having directed your attention to the good results obtained by the use of antitoxin, permit me, conclusion, to say, that I have had experience with but one patient in New York with domestic serum, this was in consultation with Dr Landes A third physician injected the antitoxin The patient died the following morning I was so much disheartened by the case that I have never since—nor had I previously used or prescribed—domestic antitoxin I believe that we are justified in prescribing a specific kind of antitoxin, just as much as we are to-day in the habit of using standard preparations to specify good drugs in other diseases

CLINICAL OBSERVATIONS IN THE TREATMENT OF DIPHTHERIA WITH ANTITOXIN

Read in the Section on Diseases of Children, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7 10 1895

BY A CAMPBELL WHITE, M D
NEW YORK.

The medical profession in America has now had an experience of about one year with the antitoxin treatment of diphtheria It is true that during the first six months the source of our supply of antitoxin was from abroad, and that this supply was necessarily limited, but during the past five or six months the supply has been about equal to the demand, and not many cases of diphtheria, particularly in the larger cities, need have suffered because of an inability to obtain serum of proper quality and strength

The desire, or ambition, on the part of the medical profession to give this remedy a trial has certainly not been lacking, for I believe I am safe in saying that nothing in the domain of medicine has so attracted the universal attention of the profession and the public the world over, as this treatment of diphtheria with antitoxin

Our National government, some of the State governments and the leading bacteriologists and clinicians of our country have manifested an active interest in testing the efficacy of this treatment In doing this, Americans have only been following the example of Germany, France and England, where the treatment has been afforded a considerably longer and much more extensive trial

It seems, therefore, as if the theory of the antitoxin treatment of diphtheria should by this time either be discarded or denounced as unsound and worthless by those who have been carefully and scientifically testing its merits all over the world, or the theory should be accepted as giving to us a remedy with which to combat one of the most fatal diseases coming under the care of the physician, and pointing the way to the successful treatment of many other dreaded diseases of bacterial origin

Have we, then, after this universal and extensive use of antitoxin any evidence or testimony to show that it does not overcome the toxemia of diphtheria, or that it is contra-indicated in the treatment of diphtheria? If so, what is the evidence, and what is the source of this evidence?

Have we any evidence or testimony that antitoxin does overcome the toxemia of diphtheria? If so, what is this evidence, and what is its source?

1 *What has the Work in the Laboratory Shown?*—The process of the manufacturing and testing of antitoxin, I consider one of the soundest proofs of its efficacy If we could find anywhere the testimony of a bacteriologist of experience that antitoxin does not save the life of a guinea pig or other animal, when this animal is injected with several times the fatal dose of the diphtheria toxin, we might then hesitate in our belief in its utility But we can not find such testimony, and have we any authority for believing that the same phenomena do not occur in man as in the guinea pig, dog, horse and other animals, when the cause of the phenomena is the same in both cases? The results in the laboratory all tend to demonstrate the feasibility of the antitoxin theory

2 *What has Clinical Study Demonstrated?*—It must have impressed every one forcibly who has followed the literature upon this subject, that nearly all the unfavorable reports have come from those whose experience has been extremely limited, that is, we see an occasional report of a case that has received antitoxin, and later died, or, sometimes a very complete report is made of an individual case, showing that after an injection of antitoxin there is a sudden development of alarming symptoms, quickly followed by death, or the patient may have lived some time after the injection, suffering all the time from symptoms which have never been seen before in the course of an attack of diphtheria In either case we are to believe that antitoxin is the factor which has caused the fatal termination Then, again, we read more reports to the effect that antitoxin has no influence whatever on the course of diphtheria, either good or bad

Before accepting these reports of extremely limited numbers of cases as an evidence against the use of a remedy which, in the experience of so many, has given such great promise of good, we should carefully eliminate the possibility of there having been other factors than antitoxin in determining the unfortunate results of these cases The entire solution at a low temperature might be injected directly into a blood vessel—the same might be true of a considerable quantity of air, for it is extremely difficult with most of the syringes used, not to have some air in the cylinder at the time of injection Either of these accidents might cause a sudden and fatal termination

Then, again, where did the antitoxin come from? Not only can a serum be put on the market containing little or no antitoxin—and it would have been easy to have sold such a serum some time ago and not very difficult now—but it is only with careful prolonged experience and costly labor that an antitoxin solution can be prepared which can be used and relied upon with perfect safety

The clinical testimony in favor of the use of antitoxin is abundant The reports, with hardly an exception, from every hospital the world over, where antitoxin has been given extensive trials, have shown most wonderful results, and these reports have included the observation of some of the most conservative and distinguished clinicians of the world In fact, nearly every report made upon a sufficient number of cases upon which to base a satisfactory conclusion is but another evidence in favor of the use of antitoxin

It has been my good fortune to see in hospital and private practice something over two hundred cases of diphtheria, varying in severity from its mildest form to its most malignant manifestation, treated with antitoxin of varying strength and obtained from different sources

The results of the first series of cases treated in this country were published by me in November, 1894[1] At that time I stated that I believed we had received in antitoxin a specific for diphtheria, in that it would prevent death from the absorption of the toxins of diphtheria, when given at the proper time and in sufficient quantity I have no reason to day to modify this statement Further experience has only confirmed the conclusions derived from the treatment of the first twenty cases

It is not my purpose to present to you a number of tables and statistics showing the value of this remedy, I hope this is not necessary I shall endeavor, as briefly as possible, to relate to you, without the use of figures, some of the clinical manifestations of diphtheria, with its complications when treated with antitoxin, and a few practical points in the administration of antitoxin

I shall first consider the effects of antitoxin upon the local conditions caused by diphtheria where the larynx is not involved

FALSE MEMBRANE

It is the common experience of all of us to see cases of "bacteriologic diphtheria" showing only a few patches of false membrane, cases which we would have undoubtedly diagnosed as tonsillitis some years ago, before we could rely upon the microscope for assistance In these cases we could hardly expect to see any difference in the results obtained with antitoxin and those obtained with our former methods of treatment Still, I think it has also been the experience of many of us to have seen these at first mild or tonsillar cases gradually or suddenly develop into the most malignant form of diphtheria, sometimes terminating fatally This, I recognize, is not the rule, but it is certainly not so very infrequent I have never seen such a case of diphtheria when treated with antitoxin take any other course than rapid recovery, and it is in this class of cases that it is so difficult to fully appreciate the value of the treatment Where the membrane is fully developed, covering to a more or less extent the tonsils, uvula, pharynx, posterior nares and nares, we have certainly occasion for alarm, and it is in such cases we want and seek more particularly for a specific

It has not been my fortune to see with the use of antitoxin any material shortening of the duration of membrane, where it has become firmly attached and seems to be a part of the mucous membrane underlying I have seen some rapid discarding of membrane before the use of antitoxin, and I have seen a few cases since, but in the latter case we could hardly claim that antitoxin was the curative agent In fact, I do not believe that antitoxin shortens the duration of the false membrane at the most more than two days, and I have never seen it "melt away in a few hours' time" We do notice, however, some change in its appearance some twelve to twenty-four hours after an injection of the serum, the edges of the false membrane become sharply defined and it may appear to have become thicker than it was before the injection This is a good omen and augurs well for the patient's recovery

The more important effect antitoxin has upon the pseudo membrane of diphtheria is its power to abort or check its further extension, and in this respect we certainly obtain the desired results This power has been well demonstrated in many cases of diphtheria when we have been obliged to forcibly remove from the nose, plugs of membrane, which completely obstructed these passages and formed a source of septemic infection Whenever this has been done before the use of antitoxin there has almost immediately been a re formation of membrane, necessitating a repetition of the operation, and I do not remember having seen but one child (the procedure has proved successful almost invariably in adults) recover after this forcible removal of false membrane from the nasal passages, while, on the other hand, recoveries have been frequent in cases treated in the same manner and under the influence of antitoxin, and in most cases there has been no evidence of the slightest tendency to a recurrence of the membrane

The influence of antitoxin on these cases I consider one of the best evidences of its efficiency

EDEMA, OR SWELLING OF MUCOUS MEMBRANE

The prognosis in all those cases which are ushered in by edema of the uvula and marked swelling of the pillars of the fauces, or where the false membrane first appears and is soon followed by this same condition of edema, is always unfavorable, and it is this form of diphtheria which gives the most pain and general discomfort to the patient Upon this condition, antitoxin exerts a most decided and satisfactory influence The patient in about ten hours finds deglutition is not accompanied with so much pain and difficulty as before It is also this subsidence of the swelling which causes the false membrane to appear thicker and more defined in outline

GLANDULAR SWELLING, OR DIFFUSE INFILTRATION OF THE NECK

This glandular enlargement of the neck which appears so rapidly in certain forms of diphtheria, especially those in which there is involvement of the posterior nares, could hardly be expected, having become fully developed, to disappear at once under any treatment, while it is the rule under almost any form of treatment for these enlargements to gradually develop until the membrane disappears or absorption of toxins ceases They rarely suppurate in diphtheria, in any case, unless it be some time during convalescence Suppuration seems to have occurred just as frequently as it did before the use of antitoxin, but the subsidence of the acute glandular swelling seems to have been accomplished more rapidly with the use of antitoxin than with other remedies

OTITIS MEDIA

The frequency of this complication seems to have been somewhat lessened, but this fact can hardly be directly attributed to the virtue of antitoxin It has been probably due to the fact that the irrigation or local treatment of the posterior nares and pharynx have been much diminished in frequency of application

SYSTEMIC SYMPTOMS

I refer by the systemic symptoms to the influence of antitoxin upon the temperature and pulse, post-diphtheritic paralysis, sudden cardiac paralysis, nephritis and the general condition of the patient

I have found no reason for changing the statement made in my first paper concerning the influence of antitoxin upon the temperature and pulse, which is as follows

"The temperature of diphtheria is so variable, being sometimes low in the most severe cases and high in others, it is impossible to tell how much it is influenced by any treatment In some of the cases the rise in temperature after the injection was marked, in others there was no decided change, while in still others there was considerable fall This fall of temperature we notice in many cases soon after the entrance to the hospital, the temperature on admission probably being the so called 'ambulance fever' Streptococci, inflammation, and other complications also give a high temperature, therefore antitoxin could have no influence on these temperatures

"The effect upon the pulse is of much more importance In nearly all cases nine hours after injection the pulse was much improved in strength, volume and frequency"

POST DIPHTHERITIC PARALYSES

As to the effect upon the post-diphtheritic paralyses, no influence seems to be exerted upon a paralysis already established Antitoxin, it would seem ought certainly to prevent, when given early in the disease, the later development of a paralysis This it does not always do, for we have seen quite a number of patients develop in the usual way post diphtheritic paralysis after having been treated with full doses of antitoxin early in the disease The same remarks apply to the sudden heart paralysis It is difficult to determine just how much the occurrence of these paralyses is influenced by the injection, but it is my impression that they are diminished in frequency and in severity, nearly all the cases showing paralysis only of the muscles of the soft palate

ALBUMINURIA, OR NEPHRITIS

Several observers have asserted that the appearance of albumin in the urine occurs with much more frequency when antitoxin is employed as a means of treatment We have used the same methods of urinary examination for albumin since the use of antitoxin as we did before, and have failed to find that the same observation applies to our cases If there has been any change at all it has been in favor of antitoxin It is possible that those who have found the appearance of albumin more frequently than formerly, have examined more carefully the urine of antitoxin patients and have even used more delicate tests If this be the case, the results are unsatisfactory unless compared with equally careful urinary analyses of patients who have not received the treatment

It will be seen thus far I have described no sudden change in the symptoms of diphtheria, either local or systemic, following the use of antitoxin I have said the false membrane does not disappear rapidly, the glandular swelling of the neck does not subside immediately, neither does a high temperature always rapidly fall Nevertheless, there is a marked change seen some twelve hours after the proper dose of antitoxin has been given *This change is chiefly in the general condition of the patient, and the improvement of some patients in this one respect is remarkable in its extent and suddenness A bad prognosis given in an individual case can, by the use of antitoxin, be changed to one of almost sure recovery within twelve hours' time*

It is this one fact which has led me to consider the remarks made recently against the use of antitoxin[3] (in spite of the fact that they come from so distinguished and careful a clinician as Dr Joseph E Winters), to be an argument in favor of its utility

Dr Winters said "I have failed to see the slightest evidence that it neutralized the toxemia in a single case I have never found that it exerted the slightest influence for good in a single clinical manifestation of the disease"

Nearly all the cases seen by Dr Winters were seen by others as well as myself Our observations differ in great measure from those of Dr Winters, who bases his conclusions upon the fact that nearly all the cases were mild and would have recovered without any treatment

Oh the other hand, we consider that more severe cases of diphtheria have entered the hospital during the past three or four months than ever before This difference of opinion is explained by the fact that Dr Winters saw the patients (this applies to a great majority of the cases), some twelve to twenty-four hours after the injection of antitoxin had been made, and some twelve to twenty-four hours after an unfavorable prognosis had been given by those who admitted the patient

For this reason I believe this difference in opinion only emphasizes the point just made, that *with the proper dose of antitoxin a bad prognosis in an individual case can be changed to one of almost sure recovery within twelve hours' time*

LARYNGEAL CASES

I can only mention these cases briefly The treatment of laryngeal diphtheria with antitoxin can not be intelligently discussed in so short a time, an entire paper could be devoted to this topic with satisfaction

It is in the laryngeal cases that we see the most marked reduction in the mortality, and this applies to the operative cases as well, either when tracheotomized or intubated

If we depend upon antitoxin only, in our treatment of this class of cases, we must resort to operative interference earlier than when we use other methods of relief for the stenosis, such as calomel sublimation, poultices applied to the neck and other recognized forms of treatment The reason for this is evident, the antitoxin not exerting much influence until at least nine hours after injection, while the stenosis may demand immediate relief

BAD RESULTS

Numerous skin lesions are seen quite frequently, generally not causing much disturbance to the patient They assume the different forms of urticaria, erythema, measles and scarlatina, and may appear at any time during the course of treatment

Some of the cases which were said to have an antitoxin rash resembling scarlatina developed symptoms of some septic infection, followed by pain and swelling of the joints There is hardly any doubt in my mind that these were true cases of scarlatina, the joint symptoms following the eruption, and in some cases the nephritis, are only additional points in confirmation of this theory I have never seen any other of the evil effects ascribed to the use of antitoxin by some observers

In conclusion, I shall endeavor briefly to mention a few of the more important points to be observed in the administration of antitoxin serum

TIME OF ADMINISTRATION

Great stress has always been laid upon the necessity of the early administration of this remedy Too much can not be said upon this subject, for, of course, no harm can possibly be done and benefit should always result from its early administration Nevertheless, I have reason to believe from experience in consultation, the magnifying of this point by nearly all writers has been the means of depriving not a few patients of the benefit of this treatment We must constantly hold in mind the fact that diphtheria is one of the most variable diseases with which we come in contact, and that the symptoms on the second or third day of the disease in one case of diphtheria may be even more fully developed than in another patient who has been afflicted for double that time, granting that both are severe forms of the disease The absorption of the toxins in one case has been extremely rapid, while in the other the absorption is slower, just as certain, and often just as fatal This difference depends upon the virulence of the bacilli, the susceptibility of the patient to the toxin, and the power to overcome the toxemia when once established

We see therefore, that we can expect better results in some cases from early treatment with antitoxin than in others that in many cases the treatment begun late in the disease may save life, and that the classification of cases treated with antitoxin according to the days upon which the treatment was begun is not by any means a sure indication of what the antitoxin has accomplished

The history of a patient seen some months ago in consultation illustrates well a point in this connection I saw the child after he had been ill seven days with tonsillar diphtheria On the evening before the child was seen by me the symptoms, local and systemic, which up to this time had been very mild, suddenly changed for the worse The false membrane began to spread and by morning involved the tonsils, uvula, pharynx, posterior nares and larynx, as evidenced by extreme stenosis The glands in the neck were also considerably enlarged I advised postponement of operative interference as long as possible and prescribed other measures for the relief of the stenosis The physician in attendance thought the antitoxin could hardly be of use as the patient had already been ill seven days I believed the antitoxin would be as efficacious in this case as if it were the second day of the disease instead of the eighth, and the antitoxin was injected The result in the case proved the latter to be true, and we felt safe the following day in assuring the mother of the recovery of her child The recovery of the child was as rapid and complete as in any case I have ever seen

We must take into consideration in each individual case the rapidity of the onset of symptoms, the general condition and age of the patient, in determining the dose of antitoxin to be administered and the prognosis to be given, and not depend too much upon the duration of the disease as a guide

SITE OF INJECTION AND PRECAUTIONS TO BE TAKEN

We must select that place which will give the least disturbance to the patient during and after the injection and which is most convenient for the operator when dealing with a refractory child If we select the extremities, we are more liable to put the contents of the syringe into some blood vessel, as we have reason to believe has been done before with fatal results The inter-scapular region or the chest are better places, but I believe, taking all points into consideration, we shall find either of the buttocks the most convenient and satisfactory situation, both to the operator and the patient They should be thoroughly cleaned with green soap and alcohol, the injection should be made deep and the buttocks should not be rubbed or massaged after injection

THE SYRINGE

We can not exercise too great care in the selection of a syringe to be used for this purpose It should be large enough to contain a single dose of the serum, it should be as simple as possible, it should contain no valves that can not be easily cleaned, and it should be such a syringe that the operator can inject a large quantity of fluid into a struggling child without the danger of the needle being pulled out before the injection is finished or even broken off and left in the child, and further, such a syringe as will preclude the possibility of air being injected

The Roux syringe up to a short time ago was the only syringe which combined to any considerable extent these requisite qualities It is elaborate, useful, expensive and can not be obtained without difficulty, as only a limited number have been imported

A syringe for antitoxin use, recently invented by Dr Cyrus Edson, is remarkable for its simplicity and utility After using this syringe on several cases I have found it quite necessary to make several changes in it, which I believe now make this syringe the most satisfactory in every respect of all the syringes used for this purpose The only defects in the Edson syringe were the straight and smooth cylinder, which allows the finger to slip during use, the direct connection of the needle to the cylinder, which does not allow of any play to the syringe during the injection, the necessity of a separate receptacle for the needle, rendering the sterilization of another tube necessary

The syringe, as modified, has the following features, which will recommend it to your use

1 The cylinder is entirely of glass and the piston of metal

2 The needles are contained in the shank of the piston

3 There is a rubber tube, which can be changed at each injection if desired, connecting the needle with the cylinder, or the syringe can be used without this tube

4 There is not a screw joint in the instrument

5 The washers are simply thin pieces of rubber,

which can be cut from an ordinary rubber bandage, and kept constantly in an antiseptic solution never to be used but once

6 The entire syringe consists of three distinct parts, viz, the glass cylinder, the piston (containing the needles), and the rubber tube All these are contained in metal cases together with a pair of thumb forceps and a bottle containing the washers, and the entire outfit, case and all, can be put in a sterilizer or boiling water and quickly and satisfactorily rendered sterile immediately before using

The accompanying figure will illustrate quite well the simplicity of this syringe

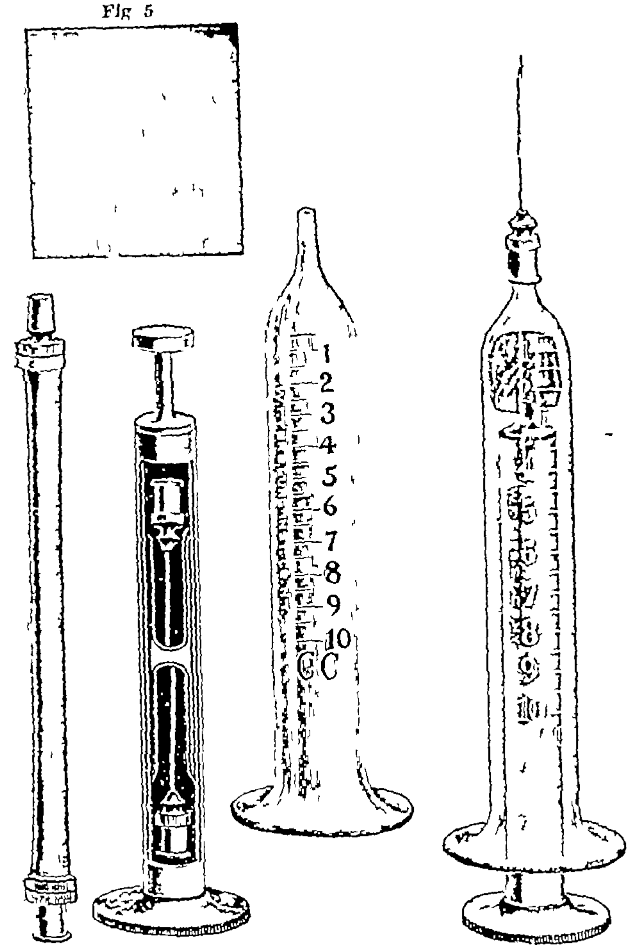

Fig 5

WHITE S ANTITOXIN SYRINGE

1 Rubber tube 2 Piston containing needles 3 Glass cylinder 4 Syringe ready for use 5 Rubber valve

IN CONCLUSION

The laboratory, with its animal experiments, the steps taken in the production of the antitoxin, the great mass of clinical evidence combined with the character of the source from which this evidence comes, leads me to believe that the antitoxin theory of the treatment of diphtheria when developed to its fullest possibilities, will prove an unfailing cure in diphtheria toxemia, and my own experience has been such as to convince me that using a reliable serum and with the exercise of ordinary care in administration, there is absolutely no danger to life through its influence upon any of the organs of the body

SOMETHING CONCERNING THE DIAGNOSIS AND TREATMENT OF FALSE CROUP

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895

BY STARLING LOVING, M D
FIRST VICE PRESIDENT AMERICAN MEDICAL ASSOCIATION 1891
COLUMBUS OHIO

False, or spasmodic croup, or mild acute laryngitis with spasm of the laryngeal muscles, is one of the every-day respiratory diseases of early childhood It is seen at all times of the year, but is most prevalent in the changeable weather of autumn and in the early part of that season traditionally but improperly called spring

Every general practitioner sees and treats it, and, when diagnosis is correct, prognosis is uniformly favorable, and treatment successful Without correct diagnosis, prognosis is wavering, treatment is lame and the most uncomfortable person connected with the case, not even excepting the patient, is the medical attendant

Discrimination is to be made between false croup and diphtheritic croup, between false and true or membranous croup, and sometimes between false croup and acute laryngitis without spasm, and between false croup and laryngismus stridulus As true croup, laryngitis without spasm, and laryngismus stridulus are of infrequent occurrence The decision commonly lies between false croup and diphtheria

It would seem that differentiation should be easy, but the diseases in their most prominent symptoms resemble each other so closely as to make it often embarrassing Still, while there are many points of resemblance there are dissimilarities, which, if rightly interpreted, render valuable assistance

False croup is sporadic, and its course and termination preclude the idea of infectiousness It is so common that the practitioner is frequently called to two or three cases in a single day, yet it is never communicated, nor does it ever assume epidemic proportions

True croup is a rare disease, so rare that though one may see a case or two in the course of a month, he may not see another for a year or two It is sporadic, and is never communicated

Apparently sporadic cases of diphtheria are not uncommon, and at times there is difficulty in tracing the infection, but when sufficient pains are taken the history of the case is easily completed Ordinarily, there is no trouble, and when after the usual period of incubation, croupy symptoms develop, there need be little hesitation in regard to the diagnosis

The onset of all the diseases to which the name croup, has been given is sudden, neither has a well-defined prodromic stage nor symptoms, yet we find events in the early history of almost every case of each which serve to guide us in discrimination

False croup is frequently preceded a few hours or for a day or two by coryza and hyperemia of the fauces, which may be accompanied by feverishness or slight fever The child may be listless and drowsy, but is usually more animated and excitable than when well, and is not inclined to sleep at the usual hour In some cases the catarrhal symptoms are more diffused, the larynx and trachea are involved, and there is cough but without stridor or spasm Ordinarily, with the development of the croupy cough there is an increase of temperature and

[2] Medical Record Nov 17, 1874.

[3] Remarks before New York Academy of Medicine stated meeting April 4 1895, and Medical Record April 20 1895

ing and non intermittent hoarseness, by the change in the voice which is soon reduced to a whisper, by the cough, which at first resembles that of false croup, but soon loses the tubular quality and becomes hissing

The larynx is more fixed and more or less tender on pressure from without The epiglottis is red and swollen, so likewise are the aryteno-epiglottidean folds, and the rim of the glottis, and now and then the false membrane may be seen Cyanosis is slowly but surely developed, is noticeable first as in diphtheria in the ends of the fingers, at the tip of the nose, and lips, and finally becomes general The stenosis of the larynx increases, orthopnea develops, prostration becomes marked and without relief there is a steady advance to a fatal termination

Acute idiopathic laryngitis, non-exudative in type, and of more severe form than has been described is not of common occurrence As a secondary disease it is occasionally seen in connection with measles, and with scarlatina, or with other diseases Sometimes it is of traumatic origin It may be differentiated from false croup by the greater intensity and persistency of the fever, by expiratory and inspiratory stridor and dyspnea, and by the character of the cough, which, though hoarse and barking, is less resonant and tubular than that of false croup

Laryngismus stridulus, or child-crowing, is also uncommon, at least in Ohio It is a purely neurotic, afebrile malady always affecting anemic delicate children, with or without rickets It is distinguished by the character of its attacks, which come without warning, is wholly spasmodic, continues for a few moments only, and recurs at intervals, short or long, through a series of months or years The diagnosis having been established, the treatment of false croup is simple and satisfactory It consists of measures adapted to the control of fever, inflammation, and nervous excitement, including spasm of the larynx The old idea that emetics and nauseants are needful for the cleansing of the stomach, and the loosening and expulsion of false membrane, was of course not well founded, but such remedies fill better than any others the objects of treatment—sedation, laxation and increase of secretion Therefore a mild emetic, or at least a nauseant should be administered as the first measure, and no medicine is more popular, nor perhaps better adapted than ipecacuanha in the form of powder or other convenient preparation I prefer the powder After emesis, a laxative dose of calomel and soda should be given, and followed by small and repeated doses of ipecac and soda, triturated with sugar of milk until relaxation is complete, and the secretions from the mucous membranes have been excited to free flow

It has appeared to me that for the purpose of maintaining relaxation, ipecac in powder, with soda, is better than any other remedy or combination This is perfectly safe, and with proper regulation of the doses the needed effect can be uniformly maintained for many hours in succession without great distress to the patient Occasionally the ipecac, especially when calomel has been administered, causes sharp purgation which is of no disadvantage in cases in which there is high fever, but, in general, when the bowels become loose the remedy should be suspended lest undue prostration result Some prefer turpeth mineral as an emetic, others apomorphia, squills, the tartrate of antimony, alum, the gillenia or American ipecac, sanguinaria, etc There can be no objection to turpeth mineral nor to alum, nor possibly to any of the remedies mentioned, but I never feel quite comfortable, after using apomorphia, until I know the time for injurious influence has passed, and I never prescribe the tartrate of antimony which, even in small doses, causes disproportionate prostration in children When the fever is high, with or without the emetic, modern doses of aconite with the sodium bicarbonate, forms a combination which fills all the indications admirably Though so powerful, it is easy to regulate the administration of aconite so that unpleasant effects may be avoided

Antipyrin and antifebrin, are both effective remedies, causing quick, nervous and arterial sedation, decided increase of the secretions of the mucous surface and of the skin, and they are reasonably safe, provided their administration is properly guarded. They, however, sometimes produce much more effect than is desired, and therefore may not be used without misgiving

Pilocarpin has greater influence on mucous and cutaneous secretions than any other medicine, and has a sedative effect on the heart I think its influence on the heart (of small doses at least) is overestimated, and that, with prudence, it may be used in the treatment of croup without risk and with decided benefit The doses should be small, even proportionally, and should be frequently repeated until the peculiar effects of the remedy upon the skin and mucous membranes become manifest In a few cases in which I have prescribed it, the dyspnea and spasmodic cough diminished as soon as the skin became decidedly moist In one case in which the temperature was 104 degrees F, and there was great nervous excitement, a tepid pack, and a few doses of pilocarpin soon brought down the fever and reduced the other symptoms One hesitates, generally, before administering opiates to young children especially in the treatment of diseases which obstruct the respiration, and hesitation is wise, but in spasmodic croup the difficulty of breathing is due almost altogether to spasm of the laryngeal muscles, and not to swelling, so that an opiate, preferably the tincture of Dover's powder, with ipecac added, can not be considered an objectionable remedy The opiate should be administered immediately after the operation of the emetic The dose should be full and should not be repeated too quickly Often a single full dose will put an end to a violent paroxysm within an hour Of the use of red iodin of mercury and of belladonna, I know comparatively little, but they are esteemed good and appropriate

Local remedies are of little service, but every one prescribes them to please anxious friends '

The room should be well ventilated, and the temperature kept at 70 or 75 degrees F

Surgical interference is never necessary in the treatment of false croup

DISCUSSION ON PAPERS OF DRS FISCHER, WHITE, KOPLIK AND LOVING

Dr Griffith, of Philadelphia—This meeting brings up a reminiscence of the meeting of the American Therapeutic Society two years ago I was convinced that the New York men had seen a vast deal more of diphtheria than we Philadelphians had ever seen I am impressed with that fact again this *morning* When it comes to the treatment of diphtheria in a large number of cases, the Philadelphia members, to use a slang expression, are not in it I see Dr Welsh, of Philadelphia, here, who is the only one among us who sees a large number We all see isolated cases, but not enough to treat the matter thoroughly by experience gained from an accumulation of facts I have had the privilege of seeing some of the cases in the Municipal Hospital treated when Dr Fischer came to Philadelphia, and have watched the treatment by the authorities

As to the value of the antitoxin treatment in diphtheria, it seems to me without question a proper treatment, and that is uttered by one who is decidedly skeptical The treatment by antitoxin I at first received with scruples, and yet so many cases have been diminished in severity by this antitoxin treatment, that if I had diphtheria it seems to me I should like to have the antitoxin theory tried in my case

I was interested particularly in Dr Koplik's paper on lacunar diphtheria of the tonsils I have seen cases where the watchers in a family have been affected with diphtheria, and we are really forced to the conclusion that those suffering with diphtheria may communicate it to others Therefore, it has been my custom, for some time, with every case of lacunar diphtheria of the tonsils to tell the family as well as I can do so without alarming them that the child ought to be isolated until we can find out exactly the gravity of the malady I am sure that I have seen cases of diphtheria begin in that way and many cases follow

Dr Welsh, of Philadelphia—I have had limited experience with the use of antitoxin in diphtheria within the last few months I hardly know just the number of cases which have come under my observation but something over a hundred I have been exceedingly anxious that antitoxin should do all that is claimed for it I feel as we all feel, the great need of a remedy for this disease, and I was very glad to learn of the great benefits that had been derived from its use in Berlin and in Italy, and in Paris, New York and other places I have been looking for these benefits, watching closely for them, observing every case closely and looking for evidence to convince me of the great value that has been claimed for antitoxin I hesitate to express any opinion in regard to antitoxin to-day, but I will say I am disappointed in its use It does not come up to my expectations, and I do not see the results that have been claimed for it In a few cases, I have seen very good results follow its use, but whether it was because of its use strictly, I am not prepared to say, for we all know it is very hard to distinguish in these cases I have seen equally well marked improvement from other treatment I do not know that I am prepared to give any statistics I have not worked out these cases carefully, but I intend doing so hereafter In the first hundred cases I injected in the Municipal Hospital, I can not say that the death rate had been reduced to any great extent My resident physician informed me that our rate had been 25 per cent while the loss at the same time from the whole number of cases was only 2 or 3 per cent more I might add that I endeavored to select the most suitable cases for injection It is true that a great many of the cases do not come to us early enough I think that ought to be stated in justice to the claims made for antitoxin We have, however, received quite a large number of cases said to have been ill only twenty four hours Others were said to have been ill forty-eight hours, and so on We have tried to limit our injections, as far as possible, to cases that had not existed longer than say four days It is true some, however, have been injected where the disease had been of some duration As I tell you in a general way, the death rate among our cases has been 25 per cent as compared with about 27 or 28 per cent perhaps, during the same period as to the whole number of cases That of course would include cases injected with antitoxin, as well as the others We have excluded all severe cases, all malignant cases, in which there seemed to be no hope Having excluded all such in the antitoxic treatment, we therefore naturally expected that the general death rate would be higher as they were thrown out I will say, on the other hand, that we did not inject mild cases where we looked for recovery under any treatment They too have been excluded

Another subject has been touched on in this discussion, and that is the diagnosis in lacunar diphtheria as I understand it It very frequently happens that we receive in a hospital, a subject, showing this form of diphtheria well marked while another child of the same family will have well marked diphtheria in which there is variance, and sometimes from the same family will be admitted a case of membranous croup in which there is no exudate whatever to be seen in the process I have no reason to believe that diphtheria assumes all these different forms, and the specific microbe is present in each Tonsillitis cases sometimes so thought, are really cases of diphtheria I am convinced that frequently, a specific microbe is found in these cases of follicular tonsillitis

The Chairman—Whose serum do you use in Philadelphia?

Dr Welsh—We have used mostly Behring's No 2 We have used, also, some of Aronson's, and some of Mulford's, and two or three bottles perhaps of the serum prepared in New York Mostly, however, it has been Behring's

Dr Thomas, of Michigan—My practice is limited entirely to private practice, and to twenty five cases The community in which I live has a population of 5,000, but it is one which diphtheria has visited frequently Our mortality has been simply frightful, averaging 75 per cent during the last twelve years that I have lived there, although I think the treatment has been the true treatment Four months ago the epidemic started again For the first of these twenty-five cases I was unable to obtain any reliable antitoxin, although I made efforts to obtain it in New York, Philadelphia and Chicago Of the first eight cases, four died Seventeen I treated with antitoxin, and, without going into any details, I will state that in each of these seventeen cases the bacilli was verified, and I have had a recovery of 100 per cent (Applause)

Now, gentlemen, this may be merely a coincidence, but those were severe cases It is where antitoxin is used before the secondary septic symptoms manifest themselves that it is efficacious I do not think you can save a case of diphtheria after it has passed into the secondary symptoms, but with my experience, I am certainly an enthusiastic advocate of antitoxin

Dr Larrabee—We have certainly had an opportunity to profit by the discussion of this subject so far that it is hardly necessary to add very much to it The enthusiasm which surrounds new treatment of disease is well known and accepted Having been a participant in that enthusiasm in 1890, with tuberculin, and having been dampened in my enthusiasm for such treatment, I have been naturally going slow with new treatments since then Whenever we report every case getting well in diseases of a fatal nature, and no deaths, the mark of suspicion is upon us We ought to be watched for a while at least (Laughter)

There are cases of diphtheria and diphtheria, and there are cases of typhoid fever and typhoid fever, and there are cases of measles and measles, and you may call it all measles, but there is quite a difference in the nature of each case It might happen to a man that he had this success which has been related, and I do not doubt it Such success as 100 per cent of recovery, and not a Dutchman's 100 per cent either, is very remarkable It means that every case gets well Such an experience as that would be a very grand one, if we could carry it out The point seems to be that we have mild cases and severe cases We may have very considerable local trouble with very slight constitutional symptoms It is in these cases that we make a test of the treatment The point seems to be that in deciding in regard to this great new treatment we might derive a little profit even from a retrospect It has been about a hundred years since the greatest inroad was made upon disease by Jenner by vaccination But it must be remembered that Jenner shut the gate of death while the throng was going through Jenner's discovery was a perfect discovery of a fact which had been observed only by a limited number, but it needed no argument The shutting of the door against the tide of smallpox was a fact It swept the earth with great destruction in that time So in that we saw a perfect discovery needing no modification or building up Now, the point in these new discoveries, I believe is well taken I believe we are on the right track I believe antitoxin is a move in the same direction as Jenner's discovery, and I regret that the profession has been a hundred years in moving upon lines that were developed by the original discoverer We do not expect after a man has been suffering seven or eight days with smallpox to vaccinate him, and have him recover thereby Jenner did not do it, and nobody else can do it, but by immunizing with serum you have the best test of its efficacy Too much stress is laid on the arrest of the disease after it has taken possession of the system and become septic You might just as well vaccinate a man when he has already contracted the smallpox

My use of antitoxin is too limited to bring it into the discussion I can revert to but sixteen cases These cases all recovered In two cases where I did not expect recovery under the old treatment, I was very greatly pleased with the results The other cases, I believe, would have gotten well under the old treatment probably I can not tell That is a point we can never discuss Dr White discussed a case here that comes to mind I never diagnose a case of croup or tonsillitis with fever that I do not have a string tied to it, so that I may pull it back after two or three days if I diagnosed it as a simple disease The fact brought out in Dr White's paper comes home to all of us, where we at first think there is no danger, and that we have only a case of tonsillitis to deal with, and where the most pronounced symptoms of diphtheria develop afterward We have a case of sore throat out our way that we call drain sore throat It is easily contracted, and if you want to make it to order you can do so at any time, if you will dig a little pit at the back door of your house, and throw the dishwater into it for a few days, and let the July sun get at it You can then have this drain sore throat I have named the bacillus of this the seweronicus

The Chairman—What does it look like?

Dr Larrabee—It has four tails, and is exceedingly lively, and hops about on several legs (Laughter) This is a thing that is communicable, and that will reproduce its kind It is as contagious a form of sore throat as any other disease You have the affection of the tonsils You will have fever and a new set of symptoms coming on the second or third day

On the subject of false croup, I want to say with all kindness, that I hope our nomenclature of diseases will be changed some time or other The false things ought to disappear, and the true things come to the surface False croup is no croup at all I think that the nomenclature would be benefited by a thorough purgation We want to get rid of a nomenclature that can only lead to error

Dr Smith, of St Augustine—Are membranous croup and diphtheria to be allowed to stand as distinct diseases, or when are they to be considered otherwise? I would be interested to hear Dr Koplik on the subject

Dr Ingalls, of Chicago—I regret very much I did not hear the papers read I feel as the Doctor feels who has just spoken, that we are probably on the right path with antitoxin, but there are a good many points that should be considered by men who are making these experiments, that have not been explained satisfactorily to my mind, at least, up to the present time The matter of diagnosis is very important indeed, and in the reported cases which have come under my notice in the journals at large, only in a comparatively limited number were the diagnoses accurately made As I came to this meeting, a gentleman told me of some one in this community who had been treating a great many cases of so called diphtheria with antitoxin This gentleman did not belong to the regular profession, and his method was when called into a house where there was a sore throat, to pronounce it diphtheria, and immediately administer antitoxin The result of his experience was that those who had been immunized had had diphtheria, while there was no proof that any one in the community had had diphtheria, and I think a great many of our reports in the journals have to do with this sort of cases

I think the effort is in the right direction, but I do not think we have very much proof at the present time My own observation has been limited, so far as I have been able to observe, benefit has followed the use of these remedies, but the experiment as a rule has not, to my mind, been satisfactory, and I find upon consulting the literature upon the subject that among the profession who ought to know most of this—the gentlemen in France and Germany, differ upon it There is a good deal of division of opinion, about one fourth of them are very sure that antitoxin is a great remedy, and about three fourths are not at all sure of it

I find in my reading only one experiment that has much weight with me In this experiment, the antitoxin was given for a few weeks and there was great improvement in the rate of mortality, when the supply of antitoxin diminished the mortality increased, and when the antitoxin was gotten again, the mortality was again reduced The mere statement that beginning at a certain time, the death rate was 50 per cent, and beginning at another time the death rate was 25 per cent, is no proof whatever We all know that the death rate in diphtheria during a bad epidemic will run up to 60 per cent and sometimes higher We know that in the beginning of the epidemic the death rate will run up to 60 per cent and a week or two later drop to 35 per cent, and then be still further reduced until all recover

On this account the experiments have not been of much value It seems to me there ought to be experiments made that would be of some value If cases as nearly alike as can be selected were treated alternately by the different methods, we might then make comparisons of value These doctors who have been so successful might have gotten hold of cases at the end of an epidemic, and those cases might have recovered even if the physician had not been there at all I hope that we are in the line of developing something that will cure diphtheria Antitoxin is young, and like tuberculin, its estimate in our opinion may have to be revised I think, however, that a physician who has an opportunity to use antitoxin and does not use it is culpable We should give the patient the benefit of every chance where there is no risk

Dr Young, of Newark—I regard antitoxin as a baby with long clothes, from which I hope for much I believe it will grow to be large The test for diphtheria, I believe, is the microscope, and that should be carried out as a test I regard diphtheria a disease as we find it and not as a germ I regard diphtheria as a systemic affection, and not local I make no applications to the throat whatever, and the results seem to be good I find that less than one in ten die when that treatment is adopted I believe diphtheria is the development of a germ within the system, although you may call it, if you please, the ptomaine of diphtheria The result of my treatment has been good, it has been entirely systemic, relying largely upon the use of pilocarpin and good nourishment

Dr Weaver, of Pennsylvania—The remarks of the gentleman from Newark, as far as diphtheria is concerned, are excellent In my country diphtheria prevails very largely I often see in one day three or four cases of ordinary acute tonsillitis, and have come to look upon those cases as dangerous In the country districts we are compelled to protect ourselves better than you gentlemen in the city hospitals We have to protect ourselves on all sides I look upon those cases of tonsillitis from the standpoint of diphtheria, if the case does not turn out to be diphtheria we are safe, and if it does turn out to be diphtheria, we are still safe The results are excellent when the treatment is begun early Within two months, two cases have come to my notice where I have used antitoxin One was the case of a little girl 7 years old She had come from Philadelphia, where she had been exposed two weeks before The case seemed mild in its incipiency, and I treated it as one of diphtheria, and prescribed accordingly I visited the patient next day In the intervening twenty-four hours the disease had spread considerably, and it looked to me as if the child was going to die A consulting physician was called, and he told the parents, in my presence, that the child would die before the next morning I agreed with him I thought that this was a case for antitoxin if there ever was one We sent for some of Gittings' antitoxin I administered a large dose, and repeated the dose in twenty four hours The effect was immediate in bringing the temperature down from 102 to subnormal The gentleman who was called in said to me "Doctor, I think the case is going to die, but if the patient gets well I will credit it to antitoxin" He did not believe in antitoxin then The child had thrown its head back, and it was impossible to give it nourishment naturally This condition existed for twenty-four hours, but the child continued slowly to improve, and finally got well I am as sure as I can be of anything that this case was saved by the use of antitoxin

There was another child in the same household suffering from diphtheria, but not so ill as the one I have just spoken of That child died through the carelessness of the nurse in letting her fall out of bed I am sure that there is power in antitoxin Of course I can not tell from one case whether it is absolutely good or bad, but from my limited experience I consider it a good thing, and I am going to use it wherever I find a case that I think demands it

Dr Ingalls—I believe the gentleman who spoke this morning said that he hoped this experimentation would continue I must differ with him in regard to this being treated as an experiment When I was in Europe in 1891, Professor Behring, in a lecture on bacteria, said that he had discovered a substance known as antitoxin that would cure diphtheria This was after the period of tuberculin fame, and the reason the physicians in Berlin would not take hold of antitoxin was owing to the great failure of tuberculin, but as these physicians in Berlin would not take hold of the substance I did not bring any to New York

It is not a year and a half ago since Professor Werniger came to the Chicago Exposition and brought me some antitoxin He asked me to use it, but I was afraid to do so I had samples sent to me from various chemic houses They called it antitoxin, but I was afraid to use it I had not then heard of Aronson's I went to Europe last year, and found there two schools of treatment by antitoxin There are two factions One is the school of Behring, who manufactures antitoxin, and who claims priority, and the second is the Aronson faction, which is a rival school, also making antitoxin, but in a different way from the process followed by Behring At a recent meeting of the alumni of the Charity Hospital, we laid down the rule that Aronson's antitoxin should be used in a dose of 5 cubic centimeters injected into the interscapular region When I hear Dr Welsh speaking of No 2 antitoxin, I tell him that since I have had more experience I use only No 3 Behring's antitoxin for healing purposes, and No 1 for immunity When I was in the hospital in Philadelphia I asked Dr Welsh to use No 3 because it was more concentrated

One of the gentlemen remarked here that he selects the malignant cases in this treatment, and does not treat the mild cases with antitoxin I treat every case of diphtheria that comes along The moment I have a patient that shows an inflamed membrane or an inflammation of the larynx, I know then that I am treating diphtheria and am justified in using antitoxin My first report showed a percentage of 5.8 mortality At that time I had some very mild cases, and the first and second days of the disease I had excellent results My second report raised the percentage of mortality from 5 8 to 15 per cent, almost three times as great, and it was due to the fact that I injected every case I saw, whether moribund or not If I thought I could save a person from drowning by throwing a rope, why not do it?

Antitoxin and serum are not synonymous terms Toxin is a condition of the blood I would ask Dr Welsh to be kind enough to use the antitoxin that I send him, and use it without skepticism When I read a paper on March 4 before the German Medical Society, Professor Jacobi said that he was happy to see such honest statistics, and rather complimented me on such a high rate of mortality If I included all the cases I had, the mortality would have been very much less

Dr Larrabee mentioned a point in the case of immunity I had a case where I refused to inject antitoxin, where it was a bad case of septicemia, and the child must die anyhow Of course the antitoxin would have done no good The Doctor asked me whether we could save the other child with an immunity dose of serum I told him I thought so, and we injected the child and it remained immune In such cases we always inject one tenth of the healing dose of serum

Dr. White—I think we put too much stress on the importance and value of statistics I think every man who has had experience in the treatment of diphtheria with or without antitoxin, can make an intelligent comparison of the value of the two treatments without consulting any figures whatever I have seen something approaching two thousand successive cases of diphtheria in the last two or three years, many of them treated without antitoxin, and quite a large number treated with antitoxin and have absolutely no hesitancy in stating that where there was antitoxin treatment of diphtheria there was improvement in almost every phase of the disease, particularly in the incubation cases, also in those cases where there is some evidence of approaching sepsis I know without consulting any statistics that antitoxin has been a benefit in those cases

It was mentioned during the discussion here that in the literature upon antitoxin about one fourth, perhaps, of the statistics were in favor of the use of antitoxin, and about three fourths undecided Certainly my reading has not led me to believe the same way I think we have a large amount of evidence in the statistics from Paris and elsewhere that is valuable There is a large number of cases in the hospitals of Brooklyn, and it has been always noticed that the mortality has diminished upon the introduction of antitoxin, and that mortality increases after antitoxin is removed from the treatment The answer to that by those who are opposed to antitoxin, is that the epidemic is mild when the antitoxin is in use, and again becomes severe when the antitoxin is taken away But if that is going to continue, it is all the evidence I want for my belief in the use of antitoxin If the disease is going to become mild when antitoxin is used, then I say there can be no objection to the use of antitoxin

Dr Fischer asked me to speak upon the use of internal medication He brought out the point that he did not expect to remove the stenosis by the use of antitoxin I think we do remove it by the use of antitoxin, but it takes ten or twelve hours to get the evidence of relief I believe also that we should resort to other methods of relief—medical methods I see no reason why we should not use the same remedies as before Antitoxin is slow in bringing about its results I have always advised the use of irrigation of the throat with a pure plain water solution of soft water I have not obtained any good results from antisepsis

I also want to express my thanks for the remarks of Dr Koplik and Dr Larrabee on the subject of having the names changed with respect to these false diseases, such as false croup and false diphtheria I think we ought to treat all cases where the bacilli are present as diphtheria It can certainly do no harm

Dr Welsh—I want to ask Dr Fischer if I understood him to say that in the selected cases where he used antitoxin, the death rate has been 15 per cent, whereas if he took all the cases in which he used it, the death rate would be as high as 40 per cent

Dr Fischer—I said that in my first series of cases the mortality was 5 8 per cent and in my second series of cases, numbering 223 the mortality was 15 11 per cent and the higher rate of mortality I attribute to the fact that I was called in consultation in many cases that were hopeless and they begged me for the sake of the family to inject antitoxin although I considered them fatal cases before I injected the antitoxin I find in looking over my record of diphtheria cases, that the mortality was about 40 per cent or over 40 per cent averaging cases of so-called diphtheria—that is croup and diphtheria—in which antitoxin never had been used. Since the antitoxin treatment has been used, the highest mortality rate in 223 cases was 15 11 per cent

The Chairman—Does this 15 11 per cent embrace all your cases?

Dr Fischer—All that I have treated

Dr Koplik—We do not know yet of any set of clinical symptoms which will distinguish the lacunar diphtheria from ordinary tonsillitis, and for that reason where the conveniences are at hand, we should always make a pathologic test of the sore throat Where the conveniences are not at hand, I think the best way in all cases of sore throat is to resort to isolation

Dr Loving—I will say to Dr White and the other gentlemen that so far as my limited experience in the matter goes, my observation corroborates exactly the statements of the papers, namely that the antitoxin is a curative remedy Koch's tuberculin was a humbug I used it in forty-five cases of tuberculosis, and every single patient was made worse by it One of the gentlemen here asked Dr Koplik to state the difference between diphtheria and membranous croup I am not much of a microscopist but whenever I can, I call in a microscopist These gentlemen practice in hospitals in large cities My practice is largely among the country population where we are not quite so subject to infectious diseases as people living in the city I find once in a while a case of membranous sore throat, where it is impossible to trace any infection The case begins as a sporadic disease and ends as a sporadic disease In the few cases where I have called the microscope into use, we have found the bacteria, the ordinary corpuscles, and that is all I agree with the other gentlemen here that there should be a correction of medical nomenclature If I had the power, I should abolish all these forms of false disease, and call them by their proper names

HYPNOTISM, WITH SPECIAL REFERENCE TO HYPNOTIC SUGGESTION AS AN AID TO THE ANESTHESIA OF CHLOROFORM AND ETHER

BY CHARLES GILBERT DAVIS, M D

CHICAGO ILL

Time is the great sieve in which is sifted the accumulated thoughts of men In it the *débris* is removed and only pure sparkling truth remains It is strange, but nevertheless true, that every great scientific advance in every department of human life is met by the most determined, and I might say, brutal opposition And yet, as the years flow on, there is ever but one result for all these conflicts, for truth is and ever will be triumphant Gradually the ignorant, stupid and cowardly attack ceases, the smoke of battle passes away, the clouds are lifted, the din of contending voices is hushed and, lo! some fair, new form is ushered upon the scene, a living, breathing reality A new star is added to the galaxy of the scientific heavens

What can exceed the bitterness of the controversy that for many years has been carried on over the subject of hypnotism, or hypnotic suggestion? It is not my intention, in this article, to review the arguments, pro and con. The salient points are constantly brought before the minds of the intelligent members of the profession, through the medical journals of the day. Neither do I wish to enter, at the present time, upon an elaborate exposé of my views of hypnotism, as to what it is, how it acts, or its application to the cure of disease. All of this will be reserved for another article, which I hope to produce in the course of time. Suffice it to say, that for many years I have carried on my experiments with an idea of determining its merits, and now I am able to say that I thoroughly believe the nineteenth century has evolved no therapeutic agent or remedial measure, all things considered, more potent or more capable of beneficent results than hypnosis.

In my address on this subject before the Psychical Science Congress of the World's Congress Auxiliary, in 1893, I said: "Surgery and hypnotic suggestion will largely constitute the healing art of the future. It may not be in our day, it may be centuries hence, but it will come." I am not at all convinced that this was extravagant language.

But without wishing to compass the entire scope of the subject relating to hypnosis in its application to disease, I wish now to call attention to its efficiency as an anesthetic, and most particularly as an aid to the anesthesia of chloroform and ether.

Ever since I became a student of medicine I have recoiled from what I call the barbarous method of forced anesthesia. I remember some of my first experiences in witnessing surgery twenty years ago in a Cincinnati hospital. Here, the patient was brought in before the class and told to breathe the chloroform, and if he did not do it willingly he was compelled to do so by being held on either side by two stout porters, while the assistant placed a handkerchief over his face, held it there and poured on the chloroform. Convulsed with terror, screaming, struggling and pleading, his whole nervous system in a furor of fright he was finally *overcome*. My observations at the time, and I have never had reason to change them, were that this method itself was almost as much of a shock as an ordinary operation. Only a few days after I began my studies there, under just such circumstances as those I have described, I witnessed a death from chloroform. Suddenly, in the midst of all this contest between the patient and assistants, she ceased to struggle, became quiet and the porters released their hold. She was dead. The post-mortem, as usual, said, "fatty degeneration." The scene impressed me, and I am sure has been a life lesson to my profit. Since then I have administered anesthetics a great deal, and had it administered under my directions by assistants thousands of times. I have never had a death. I do not boast of this, I am only glad. But I have always advised gentleness—the calm, quiet, soothing method. A few years ago the old custom was to fortify the patient previous to the operation with a glass of brandy. I believe a few soothing, assuring words spoken into the ear of most patients at the time will, as a rule, do more good than all the drugs of the Pharmacopœia.

Ever since my boyhood I have studied with interest the subject of hypnotism under its various names, phases and aspects. It has had to me a peculiar fascination. Soon after beginning my medical studies and noting the anesthesia of many hypnotic subjects, the idea naturally presented itself of applying hypnosis to produce anesthesia. Frequently I was successful, but not sufficiently often to indicate that I could rely upon this method in all cases. I have performed a number of minor surgical operations, in which I used hypnotic suggestion with entire success, to produce anesthesia.

For several years the idea has seemed to me feasible of combining in all cases, hypnotic suggestion with the chemic anesthetic. I have been led to this from observing a number of cases during the last few years where such a combination was entirely satisfactory.

In 1888 I was operating on a case of fistula-in-ano. The subject was a man about 32 years of age, very nervous, pale and weak. He got upon the operating table with fear and trembling, begged of me not to give him the chloroform, and was inclined to abandon the operation. I went to his head, closed his eyes, passed my hand quietly over his brow and then made suggestions as to what I wanted him to do, and commanded him to go to sleep. In three minutes he was quiet. Dr. J. B. S. King stood ready with the anesthetic and I motioned him to proceed, while I turned to arrange my instruments. Dr. King immediately ejaculated, "why, he is already asleep!" He had only that instant placed the inhaler to his face. Sure enough, he was sleeping soundly. I proceeded with the operation, which occupied, perhaps, ten minutes. He suffered no pain, did not resist, and was easily aroused after I had finished.

Again about six months later, I had occasion to give an anesthetic to remove a number of wire stitches from the uterus of a patient on whom I had performed trachelorrhaphy. The lady was in a very weak, nervous and exhausted state. She dreaded the anesthetic from recollections of its previous unpleasant effects. I immediately resorted to suggestion till I thought she was quieted and then asked my friend, Dr. M. S. Leech, who was present, to proceed with the chloroform. But as he placed the inhaler to her face he exclaimed: "The conjunctiva is already insensible!" No more than a single whiff of the chemic anesthetic was given. She did not resist during the removal of the stitches, was easily aroused, expressing herself as having felt no pain. Soon numerous other cases followed, in some of which a few whiffs only of the chemic anesthetic were necessary, and others required a continuance of from five or ten minutes.

In July, 1894, I delivered before the Chicago Baptist Hospital Training School for Nurses, a lecture on anesthesia, and presented before the class at that time two young men whom I knew from previous experiments to be slightly susceptible to suggestion. The first, Y. M., a young man of slender build was placed on the operating table and told he was to be put to sleep. The proper suggestions were made, the dry cone was placed over his face, and he was told to breathe deeply. He soon slept soundly and the conjunctiva was insensible. No chemic agent was employed. The second, V. P., of strong vigorous constitution, mounted the table with an incredulous smile. I produced a bottle of water from my pocket, saying I would give him a newly-discovered and more powerful anesthetic. With strong suggestions he soon yielded and slept. The conjunctiva was insensible, and he showed every evidence of thorough anesthesia.

Recently, I have made careful note of a number of cases, both with and without suggestion The following, taken consecutively from recent clinical work, are sufficient for illustration

CASES WITH SUGGESTION AND ETHER

	Time		Time
Mrs N	12 minutes	Miss M M	12 minutes
Mrs C	8 minutes	Mrs G L L	8 minutes
Mrs J	15 minutes	Mrs J B B	7 minutes
Miss S	7 minutes	Mr J G	13 minutes
Mrs H M L	9 minutes	Mrs G D B	9 minutes

Average time from beginning of ether to complete anesthesia, ten minutes

CASES WHERE ETHER WAS EMPLOYED WITHOUT SUGGESTION

	Time		Time
Mrs W B	24 minutes	Miss D C	18 minutes
Mrs G H	20 minutes	Mrs G H B	18 minutes
Mrs E	16 minutes	Mrs W A D	17 minutes
Mrs I D	21 minutes	Miss S B	18 minutes
Mrs T K	18 minutes	Mrs W C B	20 minutes

Average time from beginning of ether to complete anesthesia, nineteen minutes

There is no doubt but that any one of these patients in either of the lists might have been anesthetized more quickly than they were But in no instance was there any effort at haste, and in each individual case all due precautions were used to insure safety I am sure that the patients are often overcome, asphyxiated, as it were, by shutting off the air and crowding the anesthetic in three, four, five and six minutes, but in all the above cases the correct gradual method was employed And so far as possible, exactly the same method was used in each individual case

It will be seen from these two tables that the time necessary for complete anesthesia, is reduced nearly one half by the use of hypnotic suggestion I have no doubt that with more care a much greater reduction might be obtained

The beneficial results from using hypnotic suggestion as an aid to anesthesia are obvious

1 It calms the nervous system, and fortifies the patient to withstand the surgical operation

2 It lessens the danger of shock

3 It lessens the time, and consequently the amount of anesthetic

4 The patient awakens as if from a natural sleep

5 I believe recovery in these cases is more rapid and satisfactory

There is a wide difference between individuals as to their susceptibility to suggestion On some it has but little effect, on others it enables us to reduce the chemic anesthetic more than half, and occasionally we meet cases where it is within itself quite sufficient

It can never, when properly used, cause harm Then why not always employ it? I can not conceive of a case where it can not be applied The more intelligent the patient, the more readily we may speak to the nerve centers and have them obey Still to the insane, to the idiotic, and the unconscious babe, we may make suggestions to the sleep centers by gentle motions and soothing tones

I believe that hypnotic suggestion will, in many ways, but most particularly as an aid to the anesthesia of chemic agents, prove a blessing to mankind

THE MEANING AND IMPORT OF CASTS IN THE URINE WITHOUT ALBUMIN, AND THE INADEQUACY OF THE ORDINARY CHEMIC TESTS

BY LUDWIG BREMER, M D
ST LOUIS, MO

The microscopic examination of the urine, though resorted to more frequently now by the general practitioner than ten or twenty years ago, is still too little practiced and is underestimated as to its value by the vast majority of physicians In suspected cases of renal diseases or complications, the chemic test, frequently a very crude one, is relied upon exclusively, and in case of absence of albumin the verdict is rendered there is nothing the matter with the kidneys How erroneous such a course is on the part of the physician, what dangers it involves to the patient, what damage it may cause to the reputation of the medical attendant, and how important it is to the medical man to emancipate himself from a time-hallowed and pernicious delusion, viz, the all-importance of the chemic urinary tests, I shall try to demonstrate and emphasize in the following remarks

The diagnosis, albuminuria, is unscientific Albuminuria, as is well known is not a disease, but a symptom of a number of diseases Not only a variety of diseases but a variety of altered conditions still within physiologic limits, may give rise to the presence of albumin in the urine Thus a full meal or great bodily fatigue may cause it in some persons A certain percentage of cases of albuminuria during pregnancy also belong in this category

Now, in my experience and opinion, the presence or absence of albumin in the urine is not nearly of the diagnostic and prognostic importance, as the morphologic evidences of kidney disease, *i e*, the presence or absence of casts I venture the broad statement that a person who constantly or periodically passes urine containing casts, even without albumin, or perhaps albumin in chemically demonstrable quantities, is not in good health Such a person in my opinion has a damaged constitution, his kidneys are, to say the least, vulnerable The irritative process which gives rise to the formation of casts may not amount to an actual state of inflammation, above all there may not be the recognized somatic signs of fully developed kidney disease, and yet the subjective symptoms may be very pronounced They often are unaccountable, because sufficient importance is not attached to the presence of casts in the urine of such persons Many obscure and inexplainable nervous disorders of an apparently functional character are, however, rendered intelligible when viewed in the light of uremic or uro toxemic conditions A vulnerable kidney is naturally more easily disturbed in its function, more prone to perverted action than the normal one If it be true (and the trend of modern views and observations point in this direction) that there is an internal secretion in the kidneys, it can be easily conceived how, beside the deficient activity of the kidneys, causing a lack of elimination of the body's waste products, there may be a vitiated metabolic process in the kidneys, processes whose products are of a toxic character and when absorbed give rise to a multitude of nervous and mental symptoms From a single indisposition and malaise, from a slight soreness of the skin to the most torturing of neuraltant question was aseptic midwifery If aseptic midwifery were practiced in every case there would be no puerperal sepsis, no ophthalmia neonatorum

Dr W P Manton, of Detroit, had never had in his private practice a case of puerperal sepsis In reference to the use of the curette it is an instrument, if properly used, which is absolutely devoid of harm

Dr H W Longyear believes that when the uterus is packed full of gauze, it prevents the flow of mucus, blood and serum While more or less serum may possibly come away, fragments of placenta or blood clots will certainly be retained Rise of temperature, etc, should not be an indication for surgical interference in puerperal sepsis

Dr Wm H Myers, of Fort Wayne, emphasized the importance of differentiating between septicemia and pyemia in considering the subject under discussion

Dr C C Frederick said that out of forty cases of puerperal septicemia which he had seen in consultation in the last eight years, only two had died Nothing could be found in the uterus and there were hardly any localized symptoms

Dr James F W Ross, of Toronto, said the subject was of the greatest importance, inasmuch as a new craze at the present time had seized the profession, that of taking out the uterus in cases in which it is unnecessary, in his opinion, to remove that organ The pendulum had swung too far, as it did when the removal of the ovaries was undertaken for vague symptoms, and the Association should take some means of swinging it back again to its normal position

Dr W G MacDonald, of Albany, related a case in which he favored the use of the sharp curette

Dr Sherwood Dunn, late of Paris, France, said that in the Broca Hospital, Paris, there were 184 beds, 48 of which were devoted to obstetrical cases In his three years' connection with the hospital service there, no case of confinement had ever been followed by any septic condition

Dr A J Burgess, of Milwaukee, said in cases of uterine traumatism, especially in abortions, where there are retained septic tampons within the uterus, it is absolutely impossible to curette them away with a dull instrument He had seen the dull curette used for half an hour at a time, and yet two days afterward pieces of membranes or clots had come away, the size of a hen's egg With a sharp curette everything can be removed

Dr A H Cordier, of Kansas City, Mo, emphasized the importance of treating every case of puerperal sepsis as an individual one Where surgical interference is called for, it must be resorted to early if we expect to save lives

Dr G E Krieger, of Chicago, predicted that in time we would treat puerperal sepsis very much in the same manner as we treat diphtheria with serum

Dr J Henry Carstens, of Detroit, emphasized the importance of differentiating between the different forms of infection While the obstetrician may in some cases infect his patient, he believes in auto-infection He thinks a sharp curette is not necessary for removing the shreds of membrane or other *debris* that may be left

Dr Frederick Blume, of Pittsburg, said it had been proved years ago that in 50 per cent of healthy women there were found streptococci or other pathogenic microorganisms in the vagina He uses a sharp curette for curetting the uterus

Dr Marcus Rosenwasser, of Cleveland, Ohio, read a paper entitled, "Exceptional Location of the Blood Clot in a Case of Ruptured Ectopic Pregnancy" The case reported was an extremely interesting one, and it was presented with the hope that the knowledge of such possibility might prevent future confusion of an otherwise clear diagnosis

Dr H W Longyear, of Detroit, reported a case where a woman bled for several months On opening the abdomen, the cavity was found filled with blood and clots, and after a tedious operation he was compelled to leave some of the clots in the abdomen The patient died of shock some three or four hours after operation

Dr James F W Ross, of Toronto, reported a case of acute general peritonitis produced by the rupture of a suppurating clot After an ectopic gestation this clot was found lying in the neighborhood of the broad ligament, and was not in the least connected with the tube

Dr Edwin Ricketts, of Cincinnati, said the cases reported impressed us as to the importance of the earliest possible diagnosis The subjective symptoms should be more carefully considered

Dr W E B Davis, of Birmingham, related a case, the wife of a physician, who was delivered at full term of uterine pregnancy Then a mass was detected in the right lumbar region which continued to grow larger The patient was losing blood Operation revealed ectopic gestation The bleeding was easily controlled, a rapid operation done, but the patient died from shock Dr Davis also cited another interesting case

Dr Rufus B Hall, of Cincinnati, emphasized the necessity of early operation, or, at least, an early exploration in all instances of obscure abdominal disease After an experience of fifteen operations for ectopic pregnancy, he is more and more convinced of the necessity of early operative interference

Dr Thomas J Maxwell, of Keokuk, Iowa, called attention to transfusion with common salt solution to tide over severe cases of hemorrhage

Dr L H Dunning, of Indianapolis, followed with a paper entitled

RUPTURED INTERSTITIAL PREGNANCY

After describing the case in detail, the author drew the following conclusions

1 Ruptured tubo uterine pregnancy is more frequently fatal than ruptured tubal pregnancy, for the reasons that in the latter case the rupture frequently takes place through the abdominal end of the tube, in which case but slightly vascular adventitious tissue is torn, while in the former case vascular uterine tissue is torn Again, in tubal pregnancy not infrequently the rupture takes place through the inferior surface of the tube into the folds of the broad ligaments, and thus the amount of hemorrhage is limited, while in tubo uterine pregnancy such a rupture is rare

2 In ruptured tubo uterine pregnancy before the fifth month, unless the abdominal section is done early, the anemia will be profound, so that the patient will be unable to withstand any operation involving prolonged anesthesia and manipulation The operation should be as free from shock as possible

3 There is no pedicle to tie

4 All actively bleeding points must be secured by ligature

5 Mr Tait proposes hysterectomy as a proper procedure in such a case Unquestionably, if the patient is not too greatly shocked or anemic, such procedure would be clearly indicated

6 As a measure attended by less risk of shock, the writer proposes the tying of bleeding arteries, clearing the gestation cavity of the ovum, the establishment of free communication between the gestation cavity and the uterine cavity, the establishment of free drainage by means of tube and gauze, and finally the closure of the rent in the uterine wall by deep and half-deep sutures, or by Czerny and Lembert stitches, or instead of this method of closure, the stitching of the walls of the gestation cavity to the lower angle of the incision with the drainage from above and through the uterine cavity, and finally closure of the upper opening by tying deep sutures placed and left untied at the time of the operation This latter method will probably be found applicable only in a limited number of cases, namely, in those where the uterus is freely movable and can be brought to the abdominal wall without tension Whether the methods proposed by the writer have ever been employed, he does not know, and whether they will prove of value, a trial must demonstrate

Dr T J Watkins, of Chicago, had met with a number of cases of extra-uterine pregnancy, but none of interstitial pregnancy with rupture He had one case where the tube had ruptured, the placenta had grown fast to the cornu of the uterus, and where it was impossible to form a pedicle, the condition in the case being similar to that of an interstitial pregnancy

Dr Byron Robinson, of Chicago, was fortunate enough to examine a specimen of Mr Tait's So far as operating on these cases is concerned, it seems to him that anything other than hysterectomy means death to the woman

Dr Henry T Byford, of Chicago, said that while he had never encountered a case of interstitial pregnancy, it was very essential to know how to proceed in such cases by surgical interference

Dr A H Cordier, of Kansas City, Mo, had seen one case of interstitial pregnancy in the practice of Dr Lanphear, the uterus containing in addition several fibroids An abdominal hysterectomy was performed

Dr E T Tappey, of Detroit, read a paper entitled "Intra-Peritoneal Adhesions" He said that abdominal surgery in the last few years had established among other things, that many of the pains, vague uncomfortable feelings and so called dyspepsias are caused by adhesions of various organs in the abdominal and pelvic cavities The question of diagnosis is often perplexing, and in many instances impossible without abdominal section Wherever there is pain and palpation does not reveal any tumor or other enlargement, adhesions are one of the possible causes The author believes it proper to subject cases of chronic dyspepsia chronic and obstinate constipation, and cases of persistent pain which is caused by the accumulation of flatus, to exploratory incision to determine whether there be adhesions and for the purpose of severing them

Dr W G MacDonald, of Albany, read a paper entitled

INTESTINAL OBSTRUCTION—CLINICAL OBSERVATIONS

He said in no branch of abdominal surgery is precise diagnosis so difficult or operative procedures more taxing to the ingenuity of the surgeon At the present time, surgeons of experience are quite unwilling to give a definite opinion until the abdomen is opened and closed There are a large group of cases of ileus which may be regarded as purely symptomatic, a condition in which the continuity of the intestinal tube is interrupted, but the obstruction is due to conditions of paralysis in the intestinal wall The treatment can not always be preventive from conditions which arise during operations The enucleation of pus tubes or an extra uterine pregnancy involves the leaving of extensive denuded surfaces to which intestines readily attach themselves and those who have done secondary section can readily testify to the number of innocent adhesions found as a result of primary operations

A CLINICAL CONTRIBUTION TO THE STUDY OF THE LATERAL DISPLACEMENTS OF THE UTERUS

Dr. Edward J Ill, of Newark read this paper After reviewing the literature, the reader speaks of the importance of this abnormal condition, and thinks it has been generally overlooked, the patient's symptoms being attributed to other ailments He had collected from his last year's office case-book all cases of lateral displacements except such as come with tumors He shows that 14.2 per cent had lateral displacement He draws especial attention to those cases which he considers to be congenital and where the pain is *referred to the elongated broad ligament* The symptoms begin early in the patient's sexual life, in severer cases *progressing gradually to complete invalidism* He then relates *in extenso* several histories He describes a typical case The non operative *treatment consists of endeavoring to* elongate the shortened ligament by the use of dry wool or oakum tampons pushed between the cervix and ilium *on the* side of the shortened ligament, keeping the tampon in place by a second and third one All this is to be retained for forty-eight hours A hot douche with the patient on her knees and elbows twice daily when the tampons are *in situ*, is also ordered He related two cases of extreme suffering where total extirpation of the uterus, tubes, ovaries and broad ligament was deemed advisable after years of unsuccessful treatment, both of which are much relieved of their suffering

Dr X O Werder, of Pittsburg, read a paper on

SOME OF THE INDICATIONS AND ADVANTAGES OF VAGINAL HYSTERO-SALPINGO OÖPHORECTOMY

He said the operative results in suppurative disease of the pelvis in the hands of the abdominal surgeon form one of the proudest chapters of modern surgery While a more careful *technique* and a more thorough operation has lessened the number of fatal cases, they had not been entirely eliminated *Hysterectomy with salpingo-oöphorectomy* in suppurative disease of the pelvis not only allows us to remove the nidus of infection more completely but it gives the patient the very best chance for complete recovery without adding any additional risk to the *operation The mortality* compares favorably with that of salpingo-oöphorectomy alone He thinks hystero-salpingo oöphorec*tomy* is unquestionably the operation of the future, but whether vaginal or abdominal, still remains *sub judice* The vaginal method has many features to recommend it It precludes the possibility of ventral hernia and intestinal and omental adhesions to the line of incision, is followed by less shock because of the minimum exposure of the peritoneum during the operation, and absence of manipulation of the abdominal viscera Convalecence is more rapid and recovery more complete Two cases of vaginal hysterectomy were then reported by the author

The President, Dr J Henry Carstens, of Detroit, delivered his Address He selected for his subject

THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

The Address was replete with interesting points concerning the growth of the Association In speaking of specialists he said "What we do is not for us, but for the whole profession We think we can do more by limiting ourselves to a particular branch, and what little mite we add is not for us specialists, but is to be the inheritance of the whole profession We want the whole profession to be elevated, to become accurate and as near scientific as possible in medicine We want to raise medicine in the estimate of the laity, so that it shall not be laughed at and ridiculed in the pulpit or court room, but that it shall shine forth as an art and as a science and the noblest vocation"

Dr F Blume, of Pittsburg, read a paper entitled

ETIOLOGY OF ECLAMPSIA GRAVIDARUM

He said the etiology of this grave complication of labor is still undecided The theory, which has found the most advocates, is based upon the investigations of Lever, who first called attention to the relations between albuminuria and puerperal convulsions Lever's observations were confirmed by various authors and led to the view that the attacks were the result of blood poisoning by urea, that they were uremic and identical with those occurring in kidney diseases According to Spiegelberg, all cases of true eclampsia are of uremic origin The cause is a kidney lesion which either preëxisted or developed during pregnancy In 400 cases of eclampsia observed by Olshausen, Dührssen and Gusserow, albuminuria was present in 98 per cent Trantenroth found that albuminuria developed during the second half of gestation in 46 per cent in women whose kidneys were normal before conception took place

THE PROPHYLACTIC TREATMENT OF ECLAMPSIA GRAVIDARUM

This paper was read by Dr H W Longyear, of Detroit The author recognizes two varieties of convulsions that may occur as a result of the pregnant or puerperal condition—first, those of a purely nervous character, which usually occur in women of neurotic habit, and those who are predisposed to epileptic attacks, and second, convulsions which occur as a result of some change in the blood and tissues of the patient due to renal disease, as especially indicated by the presence of albumin in the urine

Early diagnosis is of the utmost importance to the success of any preventive treatment, and to insure this the urine of every pregnant woman should be systematically examined by the physician every two weeks after the sixth month When albumin is found to be present, immediate treatment should be begun and daily examinations of the urine made *thereafter* The author divided the prophylactic treatment into dietetic, medicinal and operative, the latter to be adopted as a last *resort* In simple cases of albuminuria without scanty secretion, many patients will do well and be *tided along to safe confinement on* an exclusive milk diet with medication

Dr W P Manton, of Detroit, *followed with a contribution* entitled

SO CALLED PUERPERAL ECLAMPSIA IN ITS RELATION TO INSANITY

The author had recourse to three sources of information—statistics from private practice, statistics from the lying-in hospitals, and the records of hospitals for the insane Never having had a case of insanity following eclampsia in his own practice, he had collected 8,868 cases of delivery reported by eight competent observers, published in current medical literature In this number he found that eclampsia is noted as having occurred thirty-*three times In not a* single instance is it stated that insanity followed the convulsive attacks During the four years 1891-1894 *inclusive*, 282 women were delivered in the wards of the Detroit Woman's Hospital, eclampsia occurring in 2 cases Both of these recovered without symptoms of mental alienation This seems the more remarkable, since of the 282 patients confined, 233 were unmarried During the same period there were admitted into the three principal asylums of Michigan *with which he is connected*, 1,271 female patients In this number, the insanity was attributed to puerperal causes in 110 instances, *but in two cases* only was eclampsia put down as the exciting cause

Dr Rufus B Hall, of *Cincinnati*, Ohio, read a paper upon

THE PREVENTION OF PELVIC INFLAMMATION IN WOMEN

He pointed out some of its most frequent causes, placing septic infection following abortion and gonorrheal infection as the most *important* He advocated the dissemination of knowledge among the laity by the family physician as a potent remedy for the prevention of these troubles He especially advocated that women should be warned by their physicians of the great *danger of* abortions in the early months of pregnancy It is well recognized by the profession that many married women produce abortion in the early weeks of pregnancy, and it is during this time that the membranes are retained and septic endometritis is induced, leading to salpingitis, pyosalpinx, and suppurating ovaries later He also advocated that the profession should impart knowledge on every legitimate occasion on the subject of gonorrheal infection in young men and boys It is well known that men frequently infect their wives, years after they themselves believe they are cured of their gonorrhea The author believes that if the profession impart this knowledge to the laity, it will only be a short time when many of the abdominal sections now made for the relief of inflammatory diseases will not be called for

Dr A H Cordier, of Kansas City, Mo, read a paper entitled

DIAGNOSIS OF INTRA-ABDOMINAL TUMORS

The author outlined the methods and procedures which should be followed in examining patients Tumors through which gases are detected by gurgling indicate either an involvement of the bowel in the tumor, or pressure of the growth on the bowel with adhesions to the same If this symptom be coupled with a history of a pyloric cancer or a cecal growth, it is confirmatory in its indications Some growths have a disposition to change positions, but all growths have one or more attachments, and it is safe to infer that this attachment is to the site at which the neoplasm had its beginning, and its movements will be only around an arc of a circle with the pedicle attachment to the diagnostic point Adhesions may prevent a growth from moving, or may anchor a tumor in a locality far from its original point of starting The history of inflammatory attacks and the pain will come to the rescue here The character of the pain and the amount and area of tenderness are invaluable aids The withdrawal of free fluid from the peritoneum will often show the presence of a tumor before undetected Pus in the pelvis is one of the easiest conditions to diagnose

Dr James F W Ross, of Toronto, read a paper entitled

PNEUMO PERITONEUM

The author reported a very instructive case of this disease He classified pneumo peritoneum as follows First, *tympanites intra-intestina* Second, *tympanites extra intestina* (*a*), traumatic 1, from without, 2, from within (*b*), non-traumatic, or spontaneous 1, without liquid, gas odorless, 2, ascites and gas odorless or fetid, 3, pus and fetid gas Third, *tympanites intra et extra intestina*

With regard to the treatment, exploration by means of a knife and the finger is free from the objection that obtains in the case of a stab in the dark by a trochar In all of these cases the author believes an exploratory celiotomy should be performed Even after the removal of the pressure on the diaphragm the breathing improves It has been stated by one operator that it is necessary in puncturing such cases to allow the gas to escape very gradually

Dr Herman E Hayd, of Buffalo, reported a case of

LARGE HYDRONEPHROTIC CYST SIMULATING OVARIAN TUMOR—ABDOMINAL HYSTERECTOMY, FOLLOWED BY RECOVERY

This case was interesting 1, on account of the large size of the hydronephrotic cyst, as well as the absence of pain or distress in its formation, 2, the obscurity of diagnosis, or, at all events, the simulation of the cyst with ovarian tumor, 3, the increased functional activity of the one kidney—in fact, its ability to vicariously functionate for the other organ, 4, the ease and facility with which the tumor was removed through the abdomen, and the uninterrupted convalescence for thirteen days, 5, at no time was albumin found in the urine, and quantitatively and qualitatively the secretion of urine was above the average At one testing, she passed 287 grains of urea in twenty-four hours There was no evidence of stone or symptoms of previous ureteritis

Dr Wm H Myers, of Fort Wayne, Ind, read a paper entitled

THE LIMITATION OF CRANIOTOMY

The author said that of late years the happy results following Cæsarean section and Porro's operation have done much to efface a dreadful feeling that we must in such cases decide whether the life of the mother or that of the child is to have preference, seeing it is now quite possible to save both The high death rate after craniotomy we must refer to the period preceding the introduction of asepsis and antisepsis The fatality of Cæsarean section has radically changed owing to the modifications in the treatment of the uterine wound, and a perfect technique, these have lowered approximately the death rate to that which is claimed for difficult embryotomy, a mortality of 10 per cent with the saving of 95 per cent of infantile life The author urges that Cæsarean section should be performed as soon as we can be assured of diagnosis

Dr Edwin Ricketts, of Cincinnati, reported three cases of gall bladder surgery, and drew the following conclusions 1, the continual absence of bile in the intestinal discharges does not necessarily signify that there is no operative condition of the gall bladder existing, 2, the bile may flow periodically, and when this is true, symptoms demanding surgical interference are generally present, 3, jaundice, when present, is very satisfactory evidence of biliary obstruction, although it is not always present, 4, pains in the region of the gall bladder coming on at intervals and in connection with jaundice, or without jaundice, in connection with clay colored stools, is positive proof of biliary obstruction, and when this is true, an operation should be resorted to, 5, persistent clay-colored stools, whether we have severe pain or jaundice with them, are the most reliable symptoms governing operative interference, 6, when a stone is primarily engaged in the gall bladder, then a pathologic lesion begins, 7, we may have an obstruction of the common duct due to external trauma, such as a blow received over the region of the liver This may produce a catarrhal condition of the common duct amounting to entire stoppage of the flow of bile, 8, we may have a solitary calculus engaged in the lower end of the gall bladder, causing thickening of the bladder wall and causing periodical escape of the infected or non infected contents, 9, we may have calculi formed in the hepatic or common duct, 10, the importance of probing the hepatic duct through the incised bladder in all cases operated upon, whether the condition present be catarrhal alone or with the presence of stone

Dr W E B Davis, of Birmingham, Ala, contributed a very interesting paper entitled

OPERATIVE PROCEDURES FOR THE RELIEF OF OBSTRUCTION OF THE BILIARY DUCTS

The author alluded to a large number of experiments which he had made on dogs, and in which he had tested the value of gauze in draining bile in injuries of the gall bladder and ducts He reported cases where he had removed the gall bladder without tying the duct by packing with iodoform gauze The animals got well In other instances where he incised the gall bladder and ducts and packed with gauze around the openings, no stitches being used, the animals recovered Complete walling off of the general cavity was noted when the abdomen of the animals was re-opened A number of cases were examined at the end of forty-eight hours Dr Davis also reported a case on the human being in which he had removed the gall bladder and a portion of the cystic duct where there was obstruction in the common duct, packed with gauze after introducing a glass drainage tube, and there was also complete walling off of the general cavity He advises that in cases of obstruction of the common duct that no attempt should be made to suture the opening after the obstruction has been removed, as the patient's condition is nearly always serious and a prolonged operation will terminate fatally The obstruction should always be removed, if possible Dr Davis' experiments demonstrate conclusively that the peritoneum is capable of taking care of a small amount of bile, but that large quantities or the constant extravasation of it will produce a fatal peritonitis usually in twenty four to forty eight hours He thinks the field of cholecystenterostomy is a very limited one

Dr W B Dorsett, of St Louis, read a paper entitled

THE USE AND ABUSE OF THE UTERINE CURETTE

The more the author had used and seen used the uterine curette, the more he was impressed with the following ideas that when used, the selection as to the shape and form of the instrument in a given case is not *always a wise one*, that a proper knowledge of its use should be obtained before trying to use it, that it is not a cure all Its use should be only in conjunction with other treatment He looks upon the blunt curette (as sold in the shops) as a dangerous instrument The instrument with a sharp cutting edge, properly constructed, is a most useful one, and in the treatment of intra uterine inflammatory conditions is the *sine qua non* of success In order to secure a good scraping instrument the sharp edge should stand at an angle of 60 degrees to the shaft or handle A greater angle will not scrape thoroughly, and a lesser angle is liable to incise the uterine wall unless used with a great deal of care Cases of perforation of the uterine wall are on record, and he thinks they are due to want of care in the selection of the proper instrument The dull or blunt curette should never and under no circumstances be used

Dr Thomas J Maxwell, of Keokuk, Iowa, followed with a paper on

SOME ANOMALIES FOUND IN ABDOMINAL SURGERY

In the first case reported by the author, he made an incision in the linea alba and discovered a reddish tumor quite unlike a pearl colored ovarian cyst The tumor was about seven inches in diameter and proved to be the uterus containing an interstitial fibroid An incision about four inches in length through the anterior fundus was made and a white fibrous tumor was shelled out with the fingers, of the dimensions of a cocoanut The incision into the uterus was closed with buried catgut sutures, fortified with one silk suture in the center of the cut A large ovarian tumor was then brought into view attached by a very broad pedicle to the right broad ligament The tumor was emptied of its contents two and one half gallons, and proved to be a monocyst The author thinks the surgeon of to day would have performed an hysterectomy He believes it is the first case where an interstitial fibroid, complicating a large ovarian tumor was enucleated, leaving the uterus intact He is of opinion that many uteri and their adnexa might be preserved by a similar procedure, and the patients left unmutilated The patient recovered Two other interesting cases were reported

SHOULD INTRA UTERINE INJECTIONS OF GLYCERIN BE USED FOR THE INDUCTION OF LABOR?

This paper was read by Dr B M Hypes, of St Louis The author concludes that these injections are often inefficient, especially so in doses under 50 c cm They are liable to be followed by shock, air embolism, thrombosis, metritis and sepsis They may and sometimes do produce glycerin poisoning—that is, decomposition of the blood corpuscles, resulting in diseases of the various organs but more especially in nephritis with hemoglobinuria The method involves no consideration of the life of the child and hence results in great mortality Its use should be abandoned, or the dosage reduced, especially in subjects with prior existing kidney affections

Dr M B Ward, of Topeka, Kan , read a paper entitled,

HAS GYNECOLOGY RECEIVED JUST RECOGNITION AS A SPECIALTY?

The purpose of this paper was to call attention to the efforts necessary on the part of the Fellows of the Society, and other members of the profession, to elevate to a position with the other specialties the standard of gynecology, and at the same time to discuss the best means to educate the profession and laity to the all-important truth that to be a gynecologist one can not at the same time be a general practitioner As specialists, our duty is clearly in the line of spreading the gospel of truth regarding the proper methods of examination and treatment of the numerous diseases peculiar to the female sex, in order that every physician shall have a reasonably intelligent understanding of the methods of dealing with the simpler forms of diseases Dr Ward said the line must be drawn, and when once fixed, strictly followed, before we can expect to command and receive just recognition as gynecologic specialists This advice must naturally mean a great financial sacrifice on the part of those who have been combining the entire field of surgery with gynecology Such a sacrifice, however, will be as bread cast upon the waters to return after many days It may even temporarily almost take the bread from the mouths of our children, nevertheless it is the only course to pursue if gynecology is ever to be recognized as a specialty whose disciples shall receive the encomiums to which they are justly entitled

Dr L H Laidley, of St Louis, Mo , read a paper entitled

SURGICAL TREATMENT OF PERFORATION OF THE BOWEL IN TYPHOID FEVER

The author in reviewing this subject concludes that an early diagnosis and operation offer the greatest chances for recovery If perforation of the bowel exists, it is the duty of the surgeon to make an exploratory incision, close up the opening and cleanse the abdomen The more rapidly the operation is made in closing the perforation which is usually single, and because of the danger in prolonging the operation, the better In selecting a method for the closure of the perforation a Lembert suture should be used in small openings, in the larger openings, when the lumen of the bowel is contracted by the use of the interrupted suture, resection with the use of the Murphy button is the most advisable course to pursue The author urges that greater interest be taken in educating the profession to select the cases, many of which are overlooked, to be placed in the hands of the surgeon and thereby reduce the mortality less than 100 per cent which heretofore has prevailed

Dr J B Murphy, of Chicago, followed with some remarks on "Typhoid Peritonitis," in which he reported some twenty-eight cases that had been operated upon by different surgeons A case reported by Dr Van Hook, of Chicago, was the first to recover Another case was operated on by Dr Abbe, and one by Dr Ill, both of which recovered Dr Murphy also reported cases upon which he had himself operated, which were followed by recovery He holds that early diagnosis and prompt operative interference offer the greatest chances for recovery

Dr H W Longyear, of Detroit, read a paper entitled

KRAUROSIS VULVÆ—A CONTRIBUTION TO ITS PATHOLOGY AND THERAPEUTICS

All of the cases of this affection seen by the author had been in women who had passed the fortieth year, and in each case the symptoms were manifested coincidentally with those experienced by the patient due to the menopause In the first case in which he recognized the disease the woman was still menstruating although irregularly, and the symptoms of the kraurosis had troubled her for about a year, the local appearance of the disease indicating that it was in an early stage of development In the second case the symptoms had been manifested for six or seven years, the patient's ovaries having been removed two years before he saw her, and before the menstrual function had entirely ceased, and the kraurosis was found to be in the advanced stage of atrophy In the third case the symptoms of the disease began with the cessation of the menstrual function, and when examined by the author four years later, the kraurosis had attained what might be called, for comparison, the middle stage The author then dwelt upon the treatment of this affection, which is both operative and medicinal

NEURASTHENIA ACCOMPANYING AND SIMULATING PELVIC DISEASE

This was the title of a paper contributed by Dr C C Frederick, of Buffalo The author defined neurasthenia as an exhaustion of the nervous system, more particularly the sympathetic nervous system, due to malnutrition After dealing with the symptoms encountered, he said there was a class of women in whom neurasthenia simulated pelvic disease It occurs in those of a nervous temperament It is a frequent ailment among our American women It is seen alike among the rich and the poor, the fleshy and rotund, as well as the thin and spare of form With reference to treatment, to correct so far as possible the habits of the patient which lead to nerve tire, general tonic treatment and good environment, and above all, the rest treatment of Mitchell, bid fair to do as much for these women as human skill had thus far devised Many of them can be nearly or quite cured, and others only partially relieved Removal of tender tubes and ovaries which are simply tender and not diseased, always adds to their suffering

The following officers were elected

President, Dr Joseph Price, Philadelphia, Pa

First Vice President, Dr A H Cordier Kansas City, Mo

Second Vice-President, Dr Geo S Peck Youngstown, Ohio

Secretary, Dr Wm Warren Potter, Buffalo, N Y

Treasurer Dr X O Werder, Pittsburg, Pa

Judicial Council, Drs C A L Reed, James F W Ross, L S McMurtry, A Vander Veer, and J Henry Carstens

On motion, the Association adjourned to meet in the city of Richmond, Va , the second Tuesday in September, 1896

Chicago Pathological Society

Regular Meeting, June 10, 1895

Weller Van Hook, M D , President, in the chair

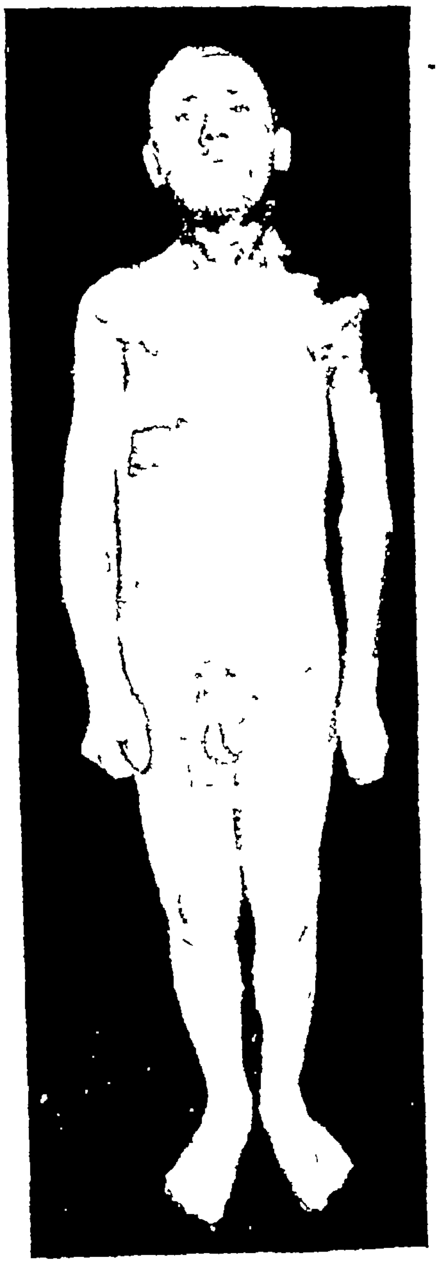
(*Concluded from p 499*)

Dr Arthur R Edwards, of Chicago, read a paper on

A CASE OF SYRINGOMYELIA WITH BULBAR CERVICAL AND LUMBAR LOCALIZATION AND ARTHROPATHY OF CERVICAL VERTEBRÆ

The patient is a Bohemian, single, aged 25 years, and a shoemaker by profession He has been in America two years and has had no previous disease His father died at the age of 70 , his mother is in good health No nervous nor other disease exists in the family of patient Uses beer moderately and denies any venereal history

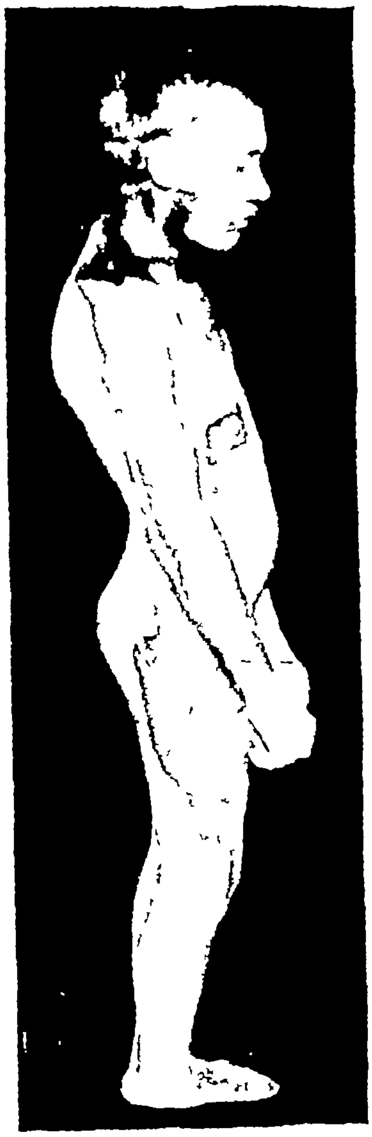
The present trouble began in May, 1893, two years before entrance into Cook County Hospital, with gastric disturbance, vomiting and eructations Hematomesis is also recounted At the same time, cramps and stiffness were observed in the arms, and in December 1893, rigidity in the legs was noticed Fibrillary contractions appeared in the arms in direct ratio to a loss of their muscular power Formification appeared eight months ago in the arms and had just been noted in the legs Constipation has existed for one and one-half years In December, 1898, a disturbance in speech alarmed the patient, but the troubled lasted only three weeks Four months later, dysphagia prevented the patient from drinking or eating fluid foods with any facility and at the present time swallowing is only effected by flexing the head strongly upon the sternum The patient at ders He has noticed no intellectual alteration The forearms tributes his loss of power to carrying loads upon the shoul- paralysis appeared at once on both sides The spinal deformity appeared a year ago, after other symptoms had inaugurated the disease The patient suffers from no pain over the spinal deformity, but rheumatic pains exist in the arms and over the trapezii muscles Pains radiate from the



shoulders into the arms, but are not severe and are most frequent in warm weather Slight pain has been experi- enced across anterior surface of ankles Regarding sensa- tion, the patient has observed that he can not feel well over the left sterno cleido mastoid muscle

Physical examination scalp, skull, nose and ears negative In pharynx, the examining finger detects a hard swelling corresponding to the spinal deformity Tongue negative , also teeth, skin, lymph glands and joints The pupils are equal and react perfectly to light and accommodation Ocular muscles Ophthalmoscopic examination negative Muscles of and facial muscles normal Intellect bright Sterno mastoids prominent on both head and neck normal Marked spinal prominence in cervical region, sides of neck Marked spinal prominence in cervical region, involving lowest three cervical vertebræ, convex posteriorly, admitting of motion in all directions without pain and

tenderness Shoulders can not be elevated very well There is marked atrophy in trapezius, rhomboidei and lv anguli scapulæ group on both sides Also atrophy and paresis in deltoid and pectoralis muscles Adductors of shoulders quite strong Extensors and flexors of elbow and supinator and pronator group fairly preserved Finger flexors distinctly weak, especially on the right side Fingers firmly flexed and rigid, resisting passive and active efforts at extension The wrist joints can be flexed and extended, but not when any considerable resistance is exerted by examiner Adduction and abduction of fingers, good upon the left and limited upon the right side Moderate respiratory expansion Abdominal muscles weak (constipation) Flexors of trunk are weak while the extensors are strong Flexors of thighs are normal on the left and somewhat weak on the right side Extensors of both hips weak and considerably spastic Knee extensors somewhat weaker, right than left, and the flexors of the same joint are markedly weaker on the right side The ankle joints can be extended and flexed with moderate freedom and force Adductors, abductors and both external and internal rotators fairly



strong As the patient stands, the kyphosis in the cervical region is very pronounced as is a compensatory lumbar lordosis The abdomen is prominent, the shoulders are decidedly round and the chin is held to sternum

There is considerable wasting of both thenar and hypothenar eminences of hands Slight wasting of forearms and in the regions most atrophied, fibrillary contractions are frequent Triceps and forearm reflexes exaggerated con- siderably Very marked periosteal reflexes Abdominal, pectoral and gluteal reflexes very marked Enormously tetanic patellar reflexes No ankle clonus Knee hip and ankle joints spastic Marked cremasteric reflexes Exter- nal genitalia negative No ataxia Marked girdle sensation across epigastrium

Sensation muscular sense perfect throughout body. Tactile sense normal everywhere save just beneath clavicles and on sides of shoulder, where complete anesthesia exists Sense of cold and heat correspond fairly well, although appreciation of heat is less preserved than that of cold The photographs fully indicate to what extent the thermo anesthesia obtains *All of the neck, part of face* near the angles of the inferior maxillæ, the chest above the nipples, a small plaque in the right hypochondrium, the extensor surfaces of both arms and fore arms, the flexor surface of the right fore arm, the finger tips to a slight degree and the antero external surface of the right thigh are the areas affected Corresponding very accurately with areas of thermo-anesthesia above outlined we find an absence of sense of pain The skin areas in which analgesia and thermo anesthesia are found are, however, acutely alive to tactile impressions

In the case presented, the main interest centers in the diagnosis, since prognosis and treatment depend logically and chronologically upon the accuracy of the diagnosis Grouping the symptoms, it is found that they fall under four main heads Those referable 1, to the pons, 2, to the cervical enlargement of the cord, 3, the lumbar enlargement, 4, to the spinal deformity

The symptoms referable to the cervical enlargement of the cord are so characteristic that from them the diagnosis of syringomyelia can be made, and with them all other symptoms and signs can be harmonized The muscular weakness and atrophy, especially of the muscles of the shoulder and of the small muscles of the hand, the fibrillary contractions and increased reflexors (wrist clonus) are characteristic of syringomyelia, when accompanied by sensory phenomena—partial or "disassociated" anesthesia The photographs indicate the sensory disturbance as dark areas, produced by painting the skin with iodin Over the dark areas there is an anesthesia to heat and cold and to pain Heat and cold anesthesia in syringomelia do not always exactly correspond, and in this case there are numerous very circumscript areas on the border of the stained area where heat sensation is present and cold is absent and *vice versa* The dark plaques represent areas where anesthesia to both heat and cold prevails Tactile sensation and muscular sense are present everywhere except where tactile sense is impaired over small areas on the neck and chest They are found even where thermo anesthesia and analgesia exist

In most instances the arm symptoms are the main findings In the present case there is a small area (indicated in the illustration) in the right hypochondrium where thermo-anesthesia and analgesia are found Also upon the antero-lateral surface of the right thigh, extending from the anterior superior spine of the ilium to the patella, is an extensive area over which the same partial anesthesia is present

A fourth complexus of symptoms relates to the basal nuclei of the last of the cerebro-spinal nerves The dysarthria and dysphagia are due to a gliomatosis in the medulla Bulbar symptoms are not rare in syringomyelia [50, 51, 52] Disturbances in deglutition are frequent (Leyden, Schultze, Westphal) Nausea and vomiting, due to irritation of the nucleus of the glossopharyngeal, occur as well as tinnitus aurium, vertigo, singultus, polyuria, amaurosis, amblyopia, unequal pupils, nystagmus Facial paralysis is rather rare (Westphal, Schultze, Grasset, Starr, Chabanne, Raïchline [62]) Paralysis of one vocal chord, of the tongue, of the ocular muscles and of the fifth nerve are recorded Disturbances in the circulatory and respiratory mechanisms occur

Multiple anatomic foci, which must be assumed to explain the separate groups of symptoms, occur in syringomyelia, either as separate deposits of gliomatous tissue or continuous gliomatous degeneration through the entire length of the cord This anatomic fact explains every symptom in the case, if we can account for the spinal deformity

A conspicuous physical sign in examination is the spinal deformity The cervical kyphosis led several examining surgeons to diagnose tubercular spondylitis and recommend suspension The difference between the two diagnoses, spondylitis and syringomyelia, in prognostic and therapeutic import is obvious The subject of arthropathy in syringomyelia has attracted but little attention

In syringomyelia, simple, painless, intermittent, obstinate hydrarthoses are observed They resemble the analogous disturbances of tabes, occur chiefly in the arms and may result in epiphyseolysis

With the preceding statement the subject of joint or bone alteration in syringomyelia is usually dismissed The most exhaustive study of the affection is that of Sokoloff [2], who collected twenty cases and described three of his own Graf added thirteen instances and Klemm reported two instances, so that some thirty six reports exist [1-3]

While considerable attention has been devoted to changes in other joints, not much has been written with reference to spinal alterations Scoliosis is frequently observed Broca [44], Morvan [4], Bernhardt [41], Roth (60 per cent, Morvan and Bruhl, *Bernhardt sixteen times in eighteen cases*, Roth five times in eight cases) Scoliosis corresponds in location to the earliest and most advanced intra medullary changes [4] Kyphosis is more rare Scoliosis and kyphosis may be explained *neuro trophic* (Kroenig) or as due to muscular weakness (Roth) Lordosis is rare In the side view of photograph of our case, the kyphosis is explained by the action of the thoracic muscles antagonistic to the posterior muscles of the shoulder girdle, second by the action of gravity, and third by trophic changes Comparison of the spinal arthropathies with those in other joints is appropriate in order to determine possible points of similarity

Sokoloff believes more joint lesions will be found in syringomyelia when greater knowledge and more common recognition of the disease prevails

In analyzing the symptoms of gliomatous arthropathies, we consider several criteria by which their existence is established

1 *Latency*—The joint affection is often overlooked by the patient or the lesion is first noted by the examining physician, who rarely can tell when the affection began

2 *Fluid in Joint*—Again, in marked contrast to tabes, the arthropathy of syringomyelia seldom produces those marked exudations which at once attract the attention of the tabetic patient Klemm [7] admits that fluid plays a subordinate rôle in syringomyelia joints, while they constitute an important factor in tabes In exceptional cases of syringomyelia, acute exudation may be observed in the joints and para-articular connective tissue, but it is usually transitory, unnoticed by patients and rarely marked in degree

Klemm has stated that fluid is more frequent in neuropathic joints than in ordinary arthritis deformans, in which exudation is comparatively rare or, if present, never so copious Even in some cases of arthritis deformans of neuropathic origin the process runs without effusion The rapidity of the secretion, its greater extent, and the invasion by the fluid of the para-articular tissues, differentiates neuropathic joints from arthritis deformans Accurate differentiation from arthritis deformans is not superfluous, as joint alteration occurring in syringomyelia may be non-exudative, the arthrite sèche of French writers Krauss [37] and Thiersch [25] recorded cases in which the primarily incorrect diagnosis of arthritis deformans was finally changed to arthropathia gliomatosa In syringomyelic and tabetic arthropathies, however, intra- and extra-articular exudation plays a prominent part

3 *Pain*—Arthritis deformans is excessively painful, while *there is no pain in neuropathic joints* A case is related[21] in which a patient painlessly opened a joint with a pair of scissors, and two cases are recorded (Czerny and Sokoloff) where the joints were resected without anesthesia This complete *or relative analgesia is* an important diagnostic datum for tabetic and syringomyelic joints Spontaneous painless fractures (three cases) and luxations also occur

4 *Extra articular bony Deposits*—It is characteristic of neuropathic arthropathies that para-articular changes occur, expressed as ossification in the soft and bony structures near the joints as well as exostoses at some distance from the articulations In syringomyelic and tabetic joints, osteophytes *are observed* external to the joint capsule in the muscles, tendons and fasciæ, while they are intracapsular in arthritis deformans—a most important and characteristic difference, according to Volkmann Rotter believes that nodes occur *only in* the lower extremities after fracture, from separation of small particles of bone Klemm combats this view and asserts that in the absence of history of joint trauma, extra-articular growths are highly characteristic of neuropathic *joint* disease *Previous* change in the soft parts probably favors osseous deposit (atrophia muscularis lipomatosa pseudo hypertrophica of Sokoloff and stretching with thickening of the joint capsule, favoring luxation)

5 *Prognosis*—Sokoloff believes that the prognosis in gliomatous joints is not always unfavorable, but rather the reverse, consisting in a subluxation alone, stretching of the capsule or an inconspicuous cartilaginous erosion, which may exist for years without progression

6 *Influence of Trauma*—Sokoloff, the most exhaustive writer on the subject, lays much stress upon trauma, emphasizing the following points *that* syringomyelia occurs in the laboring classes, that it may be easily overlooked on account of the analgesia present, and that trauma is an

important factor in tabetic arthropathy Virchow, Rotter and v Volkmann believe that trauma is always the cause[30] and that tabes is only a predisposing factor Sonnenburg's *conception*[35] is that the mechanical theory is not sufficient, that tabetic arthropathies stand in a very *intimate*, if indeed not wholly investigated, relation to tabes, and that *trauma may* produce joint disease, protract and modify its course

7 *Localization* —Rotter found 18 per cent of tabetic arthropathies in the upper and 80 per cent in the lower extremities Syringomyelic changes almost always occur in the upper extremities, a fact which can be used in differential diagnosis The pathologic changes are in the upper extremities identical in the two affections In the lower extremities, syringomyelic arthropathies occur so rarely as to prevent comparison

8 *Motility* —The joints are very movable in syringomyelia, contrasting sharply with the rigid articulations of arthritis deformans

9 *Age* —Syringomyelia occurs usually in the young, while arthritis deformans is a senile or adult disease

10 *Course* —Regarding chronicity, the gliomatous arthropathies present more chronic clinical history, in this respect resembling arthritis deformans Syringomyelia has run as protracted a course as forty-three years (*Marwedel*[29]), *thirty-six* years (Gilles de la Tourette), forty years (Déjérine)

11 *Pathology* —Anatomic differences between tabetic and gliomatous arthropathies do not exist, although local findings, either post-mortem or operative are rare The pathologic changes vary greatly, there being dropsy in some parts and hypertrophy in others Most frequently the two forms co-exist The initial change is usually degeneration in the superficial parts of the articular cartilages (Virchow and v Volkmann), while the deeper parts hypertrophy and ossify The synovial membrane thickens, relaxes and is the seat of villous growths and osseous deposits The bones are not proved to be friable, as in tabes

Regarding the pathogenesis, some writers consider the arthropathies due to trophic disturbance, since they occur with acromegaly (Karg, Charcot,[30-34], [46], [47]) and with hydrorrhachis and spina bifida[48 49]

12 *Diagnosis* —Joint affections in the upper extremities pursuing a *chronic* course without inflammatory manifestations, *producing* spontaneous dislocations, speak for gliomatous arthropathy, especially when there is joint deformity, a disproportion between the change of form and any inflammatory *symptoms* (should any exist), flail joint, crepitation and relative or complete painlessness

A cutaneous dystrophy, scars of burns, vestiges of pararitia, *muscular* atrophy in peripheral parts of the upper extremities, "disassociated" anesthesia, especially thermo-anesthesia, speak *for* syringomyelia

13 *Treatment* —Resection and immobilization have been practiced Drainage for adventitious secondary infection is sometimes indicated The therapy in other directions is that of the disease itself, *expectant and symptomatic*

2818 Indiana Avenue, Chicago

DR HUGH T PATRICK showed some microscopic preparations from cases of syringomyelia With regard to these preparations, Dr Patrick made the following *remarks* I have set up for your inspection about twenty slides, taken from five different cases of syringomyelia, and I have selected those which seem to illustrate the various conditions found in this disease The specimens speak for themselves, and I wish to mention only one or two points in connection with the pathology The first point which the specimens illustrate very well is that in the great majority of cases the process does *not originate*, as is generally supposed, in the central canal You will see in many of these specimens directly *in* front of an enormous syringomyelic cavity, the central canal perfectly normal, or simply distorted by the *pressure and* displacing influence of the pathologic process *In one* slide it can be seen that this syringomyelic *cavity has* at last invaded the central canal, and the anterior part of the cavity is lined with perfectly normal epithelium which belongs to the central canal, but has *taken* no part whatever in the pathologic *process (in the cavity formation)*

The origin in these cases seems to be in the embryonal tissues which lie just posterior to the central *canal* and which constitute the remains of the fissure *made* by the *closing* up of the spinal groove

Another point which the sections well illustrate is, *that* the various and seemingly anomalous symptoms of syringomyelia are dependent upon the varying location and size of the *central* spinal lesion *It will be seen that in* some instances the cavity invades particularly *one* sometimes both anterior horns, is sometimes almost *completely* limited to the exact center of the cord, and in *one* case affects one posterior horn exclusively In some instances again, *the cavity* has extended into the lateral *columns*, *in some cases there* is descending degeneration of the pyramidal tracts, and in others not The process is generally supposed *to consist* of a gliosis of the cord, but in some cases it is scarcely to be distinguished from a diffuse gliomatosis Two of *the sections* show this excellently well, and it is astonishing *to what* a degree the entire cord has been infiltrated and the normal tissue destroyed In this case too, the process has invaded the membranes, which are *enormously* thickened Clinically, this case passed for many years as *one* of *hysteria* One section the one in which one posterior horn alone is affected, shows the rare condition of syringomyelia limited to the lumbar region

I *also* show you sections of hydromyelus and of syphilis of the cord, either of which may closely simulate the condition of syringomyelia I would call your attention, too, to the sections showing an artificial *post-mortem* cavity in one anterior horn which so closely resembles syringomyelia that the sections were demonstrated as such by a neurologist of international reputation

DISCUSSION

THE PRESIDENT—Just a word in reference to the joint trouble or deformity in these cases of syringomyelia The *most recent* studies I *have found* on the subject of joint diseases in connection with gliosis and tabes are published in the *Deutsche Zeitschrift fur Chirurgie* by Klemm, and his conclusions are that these arthrodes found in these two diseases are of the same nature pathologically and anatomically as those which we find in arthritis deformans He finds no difference at all Probably, etiologically, great differences will be found when further *investigations* have been made on the subject

DR SANGER BROWN—I would like to ask Dr Edwards if suspension or extension has been tried in order to reduce the deformity of the neck?

DR EDWARDS—The patient has never been suspended

DR BROWN—You do not know how far it might be reduced if suspension or extension was tried

DR EDWARDS—So far as manual strength goes, you *can* not make much difference

DR BROWN—I feel thankful to Dr Edwards and Dr Patrick for allowing me to see the case and specimens I had the privilege of seeing the case before in the Cook County Hospital But I think it is a rare treat to see such a large number and variety of specimens of this rare form of disease and so far as the specimens go, they leave nothing to be desired If we had been able to have a history of each case it would simply have been a lesson in the practical physiology of the spinal cord, and I may say that a lesson in the practical physiology of the spinal cord is not so clear and definite as it was two or three years ago, that is to say, recent and more careful experiments upon the lower animals have demonstrated that the views established in reference to the sensory functions of the spinal cord are not as we have been taught for the last ten or fifteen years It has been ascertained that some of the degenerations which have formerly been regarded as dangerous in the sensory tracts were the result of clumsy and careless operations, and enough has been determined to show that our ideas hitherto held in regard to the spinal cord were not altogether sound Enough advancement has not been made to warrant us in stating at the present time just what changes we will have to make in our physiology But, as has already been stated, and as explained from these excellent sections the symptoms of syringomyelia are extremely various I asked Dr Edwards a question in reference to the deformity of the neck in his patient, simply because it occurred to me that it is quite possible that the deformity in that case was caused by a lesion affecting the muscles which support the head and as many of these muscles are rather deeply situated and might atrophy to a considerable extent without the atrophy being very appreciable to external observation, it occurred to me that the deformity might be due largely to such atrophy I can not conceive how any deformity having occurred in that situation at the outset could produce the symptoms, because the pathologic process, whatever it might be, would have to be external to the cord, and the first symptoms would have been those of compression if the disease had begun there, and it is incredible to suppose that the disease began in the cord and spread to these parts I think, to assume that the deformity in the bones of the neck were trophic is hardly feasible, inasmuch as, if they are due to trophic changes, these are the only ones In syringomyelia several types have been readily recognized and marked out, that is, a type without any material trophic manifestations, and a type in which trophic manifestations are strongly marked The latter is the type in which we have the trophic changes within the fingers, especially in the nails of both the hands and feet, and all the symptoms taking place in the bones Cases are recorded in which enlargement of the bones of the hands and of the tissues of the hands have occurred which were similar to and suggestive of acromegaly, but they probably were not the same disease

Dr Patrick spoke of the pathologic lesion as being invariably a gliosis, and I believe that in most of the cases undoubtedly the condition was a gliosis, but when this matter was up for discussion, if I remember rightly, at the last International Medical Congress held at Rome, a case was reported there in which the pathologic findings were those of leprosy, that is the bacillus of leprosy was found in the cord, there being a proliferation of tissue about the bacillus which constituted the pathologic lesion, and in the discussion it was generally conceded that syringomyelia was not at all synonymous pathologically with gliosis Any pathologic process of a progressive nature which involves and destroys these tissues in the central part of the cord will produce the symptoms, and contrary to what had hitherto been supposed, there are cases in which the leprosy bacillus is found as a cause of the pathologic process The symptoms of syringomyelia and those of leprosy have been placed side by side on account of the peculiar anesthesiæ, and the diseases have been thought of in the same connection Dr Patrick drew our attention to the fact that the disease does not begin, as we were formerly taught, in the central canal but outside of it, in the epithelial structures of which the central canal is composed In the process of closure, portions of these structures are pinched off on each side and are placed in the posterior horns

Dr Harold N Moyer—I feel there is an apology due the society for not presenting my case of anesthetic leprosy tonight I had a man looking for the patient this afternoon, and could not get him He objected to being exhibited and has grave suspicions of his trouble

I can not help referring to a few interesting analogies between the case referred to by Dr Edwards and my case of leprosy The young man first came to the clinic at Rush Medical College, for nervous diseases, and I demonstrated his case as one of syringomyelia In a subsequent conversation with Dr Patrick, he suggested leprosy to me The young man returned and I again discussed the analogy between these two affections, but neglected to ask the young man where he lived, or where he was born, but after he left the college and was walking down the street he informed me that he was born in Australia, and when 4 years of age he was taken to the Sandwich Islands and lived there a year Of course, that made the probable exposure to leprosy imminent

Regarding the symptoms, they are almost identical with the case which you have seen demonstrated tonight The anesthesia, however, extending up the limbs, on one arm to near the shoulder, the other arm to just above the elbow, on both legs to the middle of the thigh There is absolute loss of pain sense, but pressure and muscular and some degree of tactile sense remain There is also the same claw position of the hands The patient can not extend the fingers There is not the regularity of anesthesia about the shoulders such as we have here, but there are irregular patches on the side of the abdomen, chest, shoulders and on the back, more or less circular in outline, presenting at their periphery slight discoloration of the skin, which is not raised, and the cuticle is not abraded in any way We simply note in the area surrounding the anesthetic patches that the cuticle is somewhat darkened In the anesthetic portions, the skin is lighter than normal, and the anesthesia in these patches presents the same characteristics as that upon the extremities, namely, loss of temperature and pain sense, but the tactile, muscular and pressure sense is retained, although impaired

There is the same increase in the reflexes which we have here Aside from these symptoms, I think there are no differences to be noted The relation between the two diseases as pointed out at the International Medical Congress, may throw additional light upon this subject It is an interesting fact that most cases of syringomyelia have been reported by French writers and they have largely come from certain sections of France in which leprosy was exceedingly rife during the Middle Ages

Dr Hugh T Patrick—The deformities that occur in syringomyelia, especially in the type of Morvan, bring up the interesting question regarding the relation of syringomyelia to Morvan's disease I suppose most of the members know that twenty cases of Morvan's disease were described in a territory with a population of only 50,000 One of the arguments used by those who would separate it from syringomyelia was that an equal number of cases of syringomyelia had not been found, representing an equal population in other words that syringomyelia is much more rare This argument and one or two others of minor importance are about the only ones which still seem to indicate the difference of these two diseases Post mortem examinations point to their being the same disease I have seen two cases described as Morvan's disease, and I have photographs of such a case which I believe must be syringomyelia The case was seen some years ago by Dr Church and myself He had the photographs taken and I am indebted to him for them At that time, we discussed the question whether it was a case of Morvan's disease, or whether it could not be regarded as one of syringomyelia Dr Moyer in the discussion at that time said that an autopsy had recently been made in which the lesions of syringomyelia and Morvan's disease had been found, and that it was therefore, without doubt, the same disease This case manifested trophic trouble in the hands and scoliosis That leads to the question upon which Dr Brown has spoken, namely, that there may be different types of this disease, and that the different locations of the lesion will generally account for the difference in symptoms The trophic troubles begin sometimes in the soft parts, sometimes in the skin and muscles, and at other times in the bones They may begin in the upper or lower extremities The process usually starts in the cervical enlargement, so that the upper extremity is first invaded A case is reported in which it began in the lumbar region The trophic disturbance began in the toes in one case and it simulated tabes Cases are reported also where post-mortem examination has shown a combination of syringomyelia and tabes Then again, the location of the process determines the area in which the symptoms appear Sometimes the analgesia is first to appear Generally there is no anesthesia, but there may be Sometimes the trophic trouble begins in the soft parts, and then again in the bones, sometimes the soft parts are not involved at all, and the same may be said of the bones It depends a good deal upon the location of the lesion

With regard to those cases in which the bacillus of leprosy was found, I do not lend any support to that view There are only two men of note who support it, and the evidence is not sufficient from their contributions on the subject

As to whether syringomyelia in different cases may not be really a different disease, a gliosis, a central myelitis, or something else, I think such a view should be discountenanced at the present time In the majority of cases it has been shown to be a gliosis, and the symptom complex is sufficiently well known to form a distinct type of disease and the name should be limited to such Of course, the same symptoms may be produced by central myelitis I have seen one case in which an injury was followed by a central hemorrhage in the cord The case progressed slowly What the process was in that case I do not know I do not imagine in that case that there was gliosis at all It was wrongly called a case of syringomyelia A central tumor of the cord may cause the same symptoms as syringomyelia The tumor may be softened secondarily in the center, make a cavity, but I do not think it should be called syringomyelia I have seen cases of acute central myelitis with interference with pain sense with all the symptoms of acute syringomyelia, such a diagnosis being made post-mortem A few months ago Cantaninni, an Italian, publisned some cases which show the disease to be family in type A mother and three children were all affected with syringomyelia, and one of the conclusions that he draws is that in all cases of syringomyelia it is only a matter of location I do not think that is the proper and logical view to be adopted at the present time, that whenever the disease process is located in the central part of the cord, prodncing the symptoms of the disease, therefore it should be called that disease I do not think that is the proper thing to do, because the process is now sufficiently well known Other diseases produce the same symptoms as typhoid fever, but we do not call them typhoid fever

With regard to leprosy, in a given case of this disease it may be difficult to distinguish it positively from a case of syringomyelia, but such a difficulty is rare In most cases the diagnosis can be made without an examination for the leprous bacillus In the first place, the trophic trouble in leprosy affects by preference the skin, and the subcutaneous tissues, the muscles secondarily, and the bones the last of all When the phalanges are affected, they are not affected in the same way as in syringomyelia In the latter disease if the phalanges are affected, as the thumb, there is suppuration and necrosis with casting off of bone The patients many times pull out pieces of necrosed bone In leprosy there is a great deal of atrophy without suppuration In syringomyelia there are frequently secretory and vasomotor disturbances The function of the secretory glands may be affected That is rare in leprosy The skin trouble which is present in leprosy is rare in syringomyelia There are pustules in the latter disease, but no skin eruption The only skin eruption so-called in syringomyelia is a spurious urticaria from scratching caused by irritation In syringomyelia, we frequently have symptoms referable to the eye muscles, or a reflex action of the iris, or some nervous affection of the eyes There is a difference in the pupils, one pupil does not react to light as well as the other These things do not occur in leprosy In the latter disease we have only a superficial trouble of the eye, which does not occur in syringomyelia Furthermore, the anesthesia in leprosy differs from that of syringomyelia In the former disease the anesthesia is due to a multiple neuritis and it affects most intensely the periphery of the extremity and gradually approaches the trunk, in other words, the multiple neuritis, as Dr Moyer said, is along the lower extremities and extends from the feet up to the middle of the thigh That is not apt to occur in syringomyelia In syringomyelia, the anesthesia corresponds to the spinal segment If in the cervical region, it corresponds to the distribution conforming to it The anesthesia of which Dr Moyer speaks does occur in syringomyelia, but it is very rare These are the principal points in the differential diagnosis between the two diseases Ordinarily the difficulty is not very great

(*To be continued*)

SELECTIONS

Cultivation of the Gonococcus of Neisser —Redner lately exhibited a series of twenty-four hour gonococci cultures from acute and chronic gonorrhea The culture medium contained 3½ per cent agar, 5 per cent peptone, 2 per cent glycerin, 5 per cent common salt Reaction neutral The gonococci thrive well in this, and the excessive growth often seen seldom occurs He called attention to the sensitiveness of the gonococcus to fluctuations of temperature In his mind, the varying opinions of writers with regard to the applicability of Gram's method of staining to the gonococcus is due to the use of solutions of different strength, also to variations in the length of the staining and decolorizing processes Others beside Redner have noticed that if the gonococcus is overstained by standing several minutes in the concentrated anilin-water-gentian-violet solution, fifteen seconds in alcohol will decolorize, while all other diplococci, after overstaining, retain their color longer For contrast staining it is recommended to use very weak solutions, for instance, 3 drops of concentrated alkalin solution of fuchsin to 30 to 40 c c of water, applied for forty-five seconds Lewin has often cultivated the gonococcus on urine agar very successfully Varying results may depend upon the reaction of the urine Good cultures were also obtained with urine containing sandal-wood, so that the efficacy of sandal-wood against gonorrhea appears very doubtful —*Wiener Klinische Rundschau*, July 14, 1895

Mechanical Treatment of Pleurisy in St Petersburg —The movements, according to the directions of Ling and Hartelius, consist in quick elevation of the thorax of the sitting patient, twisting and bending of the trunk in various directions, with changing positions of the arms and fixation of the extremities In order to work upon the side containing the effusion, for instance the left, the movements are directed chiefly to the right, in such a way that inspiration occurs at a moment when the left side is most favorably situated to admit the air For respiratory exercises, the patient is placed on a sofa on the sound side, with a rather firm pillow, the corresponding hand remains under the pillow, the legs slightly flexed to relax the abdominal muscles, the head somewhat backward The arm of the affected side is raised up and back as far as possible In this way the sound side is in the position of expiration, pressed upon the pillow by the weight of the body, and its movements are lessened, while the affected side is in a favorable position for respiration The position of the head and arms contributes to the elevation of the ribs and so affords the auxiliary muscles of respiration the possibility of developing greater power The patient remains in this position some time, while he takes 16–20 inspirations a minute with closed mouth Meanwhile the physician massages the intercostal muscles —*Therapeutische Wochenschrift*, July 21, 1895

Union by First Intention in Nerves —Gluck presented before the Berlin Medical Society the case of a child of a year and a half, operated on May 7, 1895, for extensive tuberculosis in the right radius In the operation the radial nerve was severed After careful disinfection the nerve was sutured and then the external wound closed Primary union of the wound resulted After fourteen days, the first symptoms of restoration of the nerve were shown and after about four weeks the functions of the muscles supplied by the radial nerve became normal This is the first instance of primary union in human nerves Experimental investigations on animals show that after such nerve suturing a portion of the nerve filaments retain their vitality —*Deutsche Medicinische Wochenschrift* July 4, 1895

Pernicious Anemia.—At the Berlin Medical Society, Senator recently exhibited a microscopic blood preparation from a case of pernicious anemia, which showed very clearly those peculiar reddish corpuscles, possessing amœboid movements, which Perels denoted as characteristic of pernicious anemia Senator also found them frequently in similar cases, yet he regards it as doubtful whether they are characteristic, since he observed them in one case which could not be so diagnosed —*Wiener Klinische Rundschau*, July 14, 1895

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman Venetian Building Chicago, Ill , sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly Journal of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the Journal office

All communications and manuscript of whatever character, intended for publication in the Journal, should be addressed to the *Editor*, and all communications relative to the business of the Journal, proof sheets returned, or in regard to subscriptions, should be addressed to *The Journal of the American Medical Association*, 86 Fifth Avenue, Chicago

SATURDAY OCTOBER 5, 1895

LOUIS PASTEUR

And the King said unto his servants, Know ye not that there is a Prince and a great man fallen this day in Israel?"

Louis Pasteur, the distinguished chemist, who has contributed so largely to the scientific standing of the French Academy, died of paralysis at his home in Paris September 28, in his seventy-third year

For a period of half a century his researches and achievements have commanded the attention of the scientific world and his death will be viewed not as a loss to France alone, but as a universal calamity His career is characterized by indomitable energy, and his successes have been due to his earnest application and strict adherence to a single line of research, easily traced from his first discovery, that relating to crystallography, to those of later days Louis Pasteur, like most scientists, was often assailed by unbelievers, but guided by mathematical precision and armed with the arguments supplied by careful research, he lived to see his important theories accepted by those who were formerly most active in their denunciation So invincible did his theories prove that his colleagues became somewhat chary of taking exception to his statements, and on one occasion it is said that when a member of the Faculte de Medecine announced his intention of proving the fallacy of one of his arguments, a member of the Academy of Sciences called him aside, saying "*Beware! Pasteur is always right* "

His discoveries were those of great principles, and hosts of scientific workers were given their cue by some general principle enunciated by him, which when followed into its legitimate ramifications, seemed almost to become a new creation Thus Tyndall followed, when he demonstrated the aerial currents of bacteria Thus Lister followed, when he formulated the antiseptic plans of wound treatment, and others have walked in the rays of the same radiant light when they went a step beyond Lister, and created *aseptic* surgery

The industry, the modesty, the perseverance, and scarcely less the intense patriotism of this wonderful man, must commend his memory to posterity, by whom he will be appreciated for these characteristics almost as much as for his science

The editor of this Journal, as he writes, recalls the appearance of Pasteur as he appeared in 1890 in his laboratory, in the famous Institute erected during his lifetime as a perpetual monument to his greatness

A man of delicate frame, advanced in years, wearing a skull cap, with well cut gray beard, plainly dressed and modest in his demeanor A thoroughly pre-occupied student, was our thought, as we approached him In the pleasant interview which followed, Pasteur was informed that the first steamer built by the United States Government for the Quarantine Service was named the "Louis Pasteur " He simply expressed his thanks and bowed politely Continuing the conversation, he was told that the second steamer for the United States Quarantine Service was named the "Robert Koch " He became animated and said with much fervor "*C'est bien fait* " He evidently had great admiration for his German contemporary, there was not a tinge of jealousy "May I ask " said Pasteur, "what names you have chosen for the remainder of your quarantine fleet, as I understand from you that there are three more contemplated?" "We shall honor our own countrymen next," he was told "The third and fourth vessels will be named respectively the William H Welch and the George M Sternberg, the fifth is not yet named " "Again, well done," said Pasteur, with interest

A hurried walk with the savant and a friend through the laboratory and the museum ended this visit which, to the editor, will always be a fragrant memory and one of the pleasurable events of a lifetime

Louis Pasteur was born in the Department of Jura, Dec 22, 1822 His early education was received in the College of Arbois, from whence he entered Bensançon where he received the degree of *bachelier ès lettres*, and was appointed tutor in the same college In the intervals of his duties he followed the course of mathematics necessary to prepare him for the scientific examinations, at the École Normale In October, 1843, he entered the institution, passing fourth on the list of candidates for admission, and received his doctor's degree in 1847 He taught the physical sciences at Dijon from 1848 to 1849, and chemistry at Strasbourg until 1854 In 1857 he returned to Paris and took charge of scientific instruction in the École Normale, where he remained until 1863, at which time he became professor of geology, physics and chemistry in the School of Fine Arts. He was appointed professor of chemistry at the Sorbonne in 1867 and remained in that position until 1875. In 1868 he was retired with a pension. From 1886 most of his work was at the Pasteur Institute.

His first triumph was in crystallography when he discovered the "left-handed" tartaric acid and the constitution of paratartaric acid. For his researches on the relations of the polarization of light to hemihedrals in crystal he received the Rumford medal from the Royal Society of London. His next achievement was the theory of fermentation and was followed by a series of studies on the manufacture of vinegar and studies on wine. In 1865, at the request of the civil authorities, he directed his investigations to the diseases of silk worms, which were ruining that great industry in France. For three years he was actively engaged in the study of this disease, and when he had arrived at a solution of the problem, which was to the effect that all unhealthy moths should be rejected and destroyed in order to prevent infection, he was stricken with paralysis, from which he never fully recovered. In 1860 he exploded the theory of spontaneous generation at the Academy of Sciences. He next took up the problem of splenic fever, from which he passed to fowl cholera, at the same time directing his attention to Jenner's discovery of vaccination. He communicated to the Academy of Sciences the important facts that sheep and cows vaccinated with the attenuated bacilli were protected from subsequent inoculation with virulent virus.

Of these remarkable discoveries Pasteur said: "I have lent to the expression vaccination, an extension that I hope science will consecrate as a homage to the merit and immense services rendered to humanity by one of the greatest men of England—Jenner."

His next great work was on hydrophobia, and his first case was upon a boy named John Meister. His theories on this subject have continued to gain credence and are now accepted by the majority of scientists. His discoveries in relation to chicken cholera clearly forestalled the antitoxin hypotheses in treatment.

In 1887 the Institute Pasteur was built by public subscription and the average number of inoculations has been nearly one hundred a day.

In 1892 the municipal council of Dôle placed a commemorative tablet over the door of the house in which he was born.

ON THE INFECTIVITY OF THE URINE IN TYPHOID FEVER

Two professors of the British Army Medical School at Netley make a joint contribution to the London *Lancet* touching the important rôle played by the typhoid bacillus in the urine of patients suffering from typhoid fever. Their names and positions are A. E. Wright, professor of pathology, and D. Semple, Surgeon-Major, assistant to professor of pathology.

Their examinations for the article in question were seven in number, the most approved methods of bacterial investigation being employed by them. In six of the cases the bacillus was readily detected in the urine, and this fact, they claim, should bring into greater prominence the diagnostic value of bacterial work in doubtful cases of fever. The writers are free to admit that the presence of typhoid bacilli in the urine is not a new fact. It has heretofore been pointed out by Sanerelli, working under the auspices of Metschnikoff, and by them made the basis of a new theory, namely, the theory of blood infection in contradistinction to the intestinal intoxication process theory, which is the one that is now generally worked under by the profession. Their line of argument begins with the parity of pathologic processes that takes into consideration the conditions of organs remote from the intestinal tract, in the case of this fever, as compared with certain other febrile diseases. One of the phenomena first to be explained, they assert, is turgidity of the spleen and the presence of typhoid bacilli in the splenic tissue.

"Now, this turgidity of the spleen and this presence of microorganisms in the splenic tissue is an invariable accompaniment of every septicemic process. We find it in the case of such blood infections as anthrax in cattle and spirillum fever and malaria in man. And we have the explanation of this phenomenon in the experiments of Werigo, which show that the introduction of any foreign particulate matter into the blood invariably results in a deposition of that particulate matter in the spleen (and other internal organs), and in an aggregation of polynuclear white blood corpuscles round the foreign particulate matter, and finally, in a process of phagocytosis. Everybody who has a rabbit, and a little carmine, or any bacterial culture at his disposal, can readily verify these facts for himself. The enlarged spleen and the presence of bacteria there are thus quite in harmony with the theory of a blood infection in typhoid fever. The fact that the white blood corpuscles are diminished in the circulating blood in typhoid fever is also in harmony with this explanation. We have further, in connection with typhoid fever, to account for the eruption of pink spots on the skin. These were inexplicable on the intoxication theory of typhoid fever. They are, however, of the easiest explanation if we make the assumption that typhoid fever is characterized by a blood infection, for here, as in other cases, we may instance the skin eruption in the case of human glanders, the spots evidently corresponding to lodgments of the bacteria in the capillaries of the skin. This interpretation of the skin eruption in typhoid fever has been borne out in the case of typhoid, just as it has in the case of glanders, by the fact that the specific bacteria have been cultivated from the spots."

The writers quote the findings of Wathelet in his series of investigation of the stools of typhoid patients.

His object was to answer the question as to whether, in addition to the bacillus coli communis, the true typhoid fever bacillus is not also to be found in the stools of patients suffering from typhoid fever The following are the results of WATHFLET's careful examination of this question The true typhoid fever bacillus was detected in the stools of only four of the twelve cases of typhoid fever which were studied by this observer In the case of these four patients the typhoid fever bacillus was detected only four times in a total of twenty-four examinations, and even on these four occasions the true typhoid fever bacillus was outnumbered by the bacillus coli communis in the proportion of about 3 to 1 In the case of the other eight cases of typhoid fever the bacillus appeared to be absent from the stools throughout the whole course of the disease WATHFLET has further shown that if the bacillus typhosus and the bacillus coli communis are implanted into one and the same tube of nutrient broth, the bacillus coli communis will outgrow and kill off the typhoid fever bacillus, even when at the outset an enormous numerical preponderance is given to the typhoid bacillus over the bacillus coli communis Again, WATHFLFT has shown that whereas the bacillus coli communis will flourish in a nutrient medium containing the toxins elaborated by the typhoid fever bacillus, the typhoid fever bacillus will not grow in a nutrient medium containing the toxins elaborated by the bacillus coli communis "

The conclusions of DRS WRIGHT and SEMPLE may be summarized under four principal heads namely

"1 It is true that the typhoid bacilli are present in the urine of patients suffering from typhoid fever, and if, as we shall see typhoid bacilli are generally absent from the feces, it will be evident that it is the urine, and not the feces, of patients suffering from typhoid fever which is responsible for the spread of typhoid infection

"2 If typhoid bacilli are constantly present in the urine of typhoid patients, it may be possible to diagnose the presence or absence of typhoid fever by undertaking a bacteriologic examination of the urine

"3 If it is true that typhoid bacilli are constantly present in the urine in cases of typhoid fever while they are generally absent from the feces, it will be evident that the conception of typhoid fever upon which the ordinary clinician proceeds is an entirely erroneous one

"4 The working hypothesis regarding this fever, in the minds of medical men generally favoring, as it does, the notion that this fever is an intestinal intoxication process should be revised, and substituted for it, one that will have regard to the wide range of pathologic appearances, some of which at least fit in well with a hypothesis of blood infection, such as malarial fever in man and anthrax in cattle "

The importance of thoroughly disinfecting the urine of typhoid patients rather than the feces is insisted upon, as the great hygienic lesson to be learned in this view of the case They say

"We thus see that in six out of seven cases examined, the typhoid fever bacilli were easily detected in the urine In view of this fact it seems to us that the bacteriologic examination of the urine ought not to be neglected in any doubtful case in which typhoid fever is suspected It is hardly necessary to do more than merely advert to the hygienic aspect of the matter It was only a natural outcome of the intestinal intoxication theory of typhoid fever that the greatest precaution should have been enjoined with regard to the stools of the patient suffering from typhoid fever while the disinfection of his urine was neglected If, however, the recent observations on the almost constant absence of typhoid fever bacilli from the stools are to be trusted, the disinfection of the feces will have to rank not as an article of faith, but as a mere "counsel of perfection " On the other hand, the most careful attention will have to be given to the disinfection of the urine In some cases the urine even before incubation is absolutely turbid with typhoid bacilli "

CONCERNING GALL-STONES

Gall-stones are a rather common phenomenon in the daily work of a physician with a large practice In fact, they are so common as to lull the vigilance of the unwary practitioner, and these notes are for the purpose of directing attention to some of the curious conditions connected with their presence, and to show that they are often an unmixed evil To begin, then, with their frequency It is commonly stated that from 4 to 12 per cent of individuals are affected with gall-stones This figure has been copied for many years and is probably too high PAULSEN, of Copenhagen, has recently published statistics showing that in Denmark this per cent is decidedly too high During the period 1870–1890, only 111 cases—30 men, 81 women—of cholelithiasis were treated in the Communal Hospital of Copenhagen During these years 9,172 necropsies were performed, and calculi were found in but 3 78 per cent

Mankind enjoys no monopoly of these concretions, for they are found in most vertebrates, especially in stall-fed oxen, and in mollusks and insects among the invertebrates As regards number, they may range from one up to hundreds and even thousands —7,802 seems to be the high-water mark thus far

The size of gall-stones ranges from mere detritus—*sable*, as they say in French—up to masses of several square inches It is given to but few persons to harbor a concretion measuring four and a half by two and a half inches, yet such a stone was recently removed from an old woman in England who otherwise was not at all remarkable Fresh calculi are always heavier than water and only float after becoming dry, hence, in washing fresh feces to discover them, they will be found at the bottom and not at the top of the vessel It may be noted that GERHARDT asserts lately that physical diagnosis of biliary calculi can be made, even before any pain is present, by this palpable tumor which disappears when the stone passes into the bowel The

CORRESPONDENCE:

Library of the American Medical Association

CHICAGO, Sept 25, 1895

To the Editor —For the first time in several years, if not in its history, this library has been united and roughly sorted into periodicals, transactions, monographs and pamphlets There are about two hundred and fifty incomplete sets of periodicals, mostly United States, with some English, French and a few German, Italian and Spanish Some of these, mostly the older United States periodicals, have been bound in a cheap but durable style, but the greater majority are unbound This number includes some not now received in exchange, but this deficiency is made up by new periodicals, so the number remains about the same

By the terms of the contract, the library does not receive *all* periodicals and books sent to the JOURNAL Some of these are kept for office copies and some become the property of the reviewers The value of these sets is their incompleteness, as enabling the Newberry Library to fill up many of the deficiencies in its sets, particularly of the United States periodicals, a procedure which has been anticipated for some time

There are some good things in the older United States periodicals, those now extinct For instance, there is almost a full set of the New York *Journal of Medicine*, sometimes called *Purple's Journal*, from the name of the most prominent editor This was in some sense the forerunner of the present *New York Medical Journal*

There is also a set, fairly complete, of the *Medical Repository*, edited by Samuel Latham Mitchell, a distinguished New York physician and United States Senator Started in 1797, this periodical turned the century and ran until 1824, to be practically succeeded by *Purple's Journal*, and this, later, by the present *New York Medical Journal*.

The *Philadelphia Journal of Medical and Physical Sciences* is nearly complete This is the direct antecedent of the *American Journal of the Medical Sciences* Strange as it may seem, the proverb of the shoemaker's child comes true in this library, for there is not a set or even a volume of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

The Canadian journals are well represented, as also are the Central and South American periodicals These latter are valuable as an exponent of what is being done in these countries which are so near to us, and which are opening such prosperous fields for commerce

There are also a few French and German periodicals About one hundred and thirty societies are represented by their Transactions, and in the majority of cases these Transactions as well as the periodicals are unbound

Nearly all of the State medical societies are here, and the various local and national societies also There are some valuable foreign Transactions, and these, as is well known, can only be secured by exchange With the State Transactions already in the Newberry Library, these will, in many cases, make complete sets The AMERICAN MEDICAL ASSOCIATION heads the list with a full set of its own Transactions and the Index

As to monographs or books, there are no especially rare or valuable works in the collection A few old English works have drifted in, and these will be noted

Heister, Lawrence Medical, Chirurgical and Anatomical Observations, vol ii, London, 1755, quarto This copy has lost both covers, and in addition the bands have been torn through It is a raised band book, and why the vandal should have spoiled it by tearing the bands out is a mystery

Astruc, John Treatise of Venereal Diseases in Nine Books London, 1754, quarto There are two copies of this work

Mead, Richard Medical Works, London, quarto, 1762 Has a fine portrait of the author as a frontispiece

Winslow, J B An Anatomical Exposition of the Structure of the Human Body, 3d edition, two volumes in one, London, 1769, quarto

There is an edition of Boerhaave in six volumes London, 1742–1746

Van Swieten Commentaries on Boerhaave's Aphorisms Eighteen volumes 1766–1776 This has the stamp and signature of Dr John Redman Coxe, a well-known Philadelphian, a man of note, a teacher, and editor of a dispensatory, who was born in 1773 and died in 1864

There are two sets of works of Benjamin Rush, easily the first man in United States medicine

There is an imperfect copy of the sixty volume, 1812–1822, Dictionnaire Encyclopedique

The bulk of the books are those received during the last fifty years and represent all branches of science There are comparatively few standard books among them The pamphlets are largely reprints, but there are scores of hospital reports, health reports and college catalogues The card catalogue and accession register, both of course imperfect and incomplete, are also here These show that an attempt was made to carry on the library as a library

The collection is now where it will do the most good, that is, in completing another and larger collection It never was a library, simply a mass of unorganized matter

Newberry Library G E WIRE, M D, Librarian

Tuberculous Patients—a Misquotation Corrected

ST LOUIS, Sept 27, 1895

To the Editor —In the JOURNAL of September 21 (in the report of the Society Proceedings), I am represented as having said at a discussion of the Mississippi Valley Medical Association, at Detroit, Mich, that tuberculosis patients could not live in Colorado or New Mexico, that they would be *more apt to die there quicker than anywhere else* I beg to say to you that I have never made such a remark anywhere, and that your reporter must have mistaken my statement I did say something to the following effect "That patients suffering with acute tuberculosis do not find *Colorado or New Mexico* climate favorable, and that in suc altitudes acute *tuberculosis runs* its *course* more rapidl than elsewhere at low altitudes" I had in mind simpl acute tuberculosis, and nothing else Please publish thi letter in a prominent place among the Society Proceeding *in order* that those to whom any injustice is done by th *misquotation may read it I remain,*

Very truly yours, PAUL PAQUIN, M D

A Correct Nomenclature

LA FAYETTE, IND, Sept 28, 1895

To the Editor —There is a growing tendency by physician to call their practice by the name of "business" While th practice of medicine has its business side, which should b carefully guarded, it surely is not all business, except wit those fellows who prostitute the practice to get out of it a the money they can, by leaving out of sight all the othe attributes which characterize a good physician's practic When a physician calls his practice "business," we naturall look for those tricks of trade which are reprehensible in th practice of medicine Often we do not have to look far find them either In the name of the good system und which we were reared, let us cease to lower ourselves in th estimation of others by calling what we do "business," b rather let it be known by the name by which it has alwa previously been called, "practice"

Fraternally, GEO F KEIPER, M D

BOOK NOTICES

Fuller on Male Sexual Disorders Disorders of the Sexual Organs in the Male By Eugene Fuller, M D, Instructor in Venereal and Genito-Urinary Diseases, New York Post Graduate Medical School In one very handsome *octavo volume of 238 pages with 25 engravings and 8 full-page plates* Cloth, $2 Philadelphia Lea Brothers & Co, Publishers 1895

This book contains seven chapters, as follows Anatomy, Physiology, Pathology, Clinical Features, Differential Diagnosis, Treatment and Prognosis, and Illustrative Instances

In this work the author correctly says that the anatomy, which lies at the foundation of all medical science, should properly precede any discussion of a subject, and proceeding therefrom, the physiology and pathology follow in logical sequence The book, which is a valuable one as far as it goes, seems to be devoted much more to diseases of the vesiculæ seminales than to any other affections, and, strictly speaking, its title should be sexual disturbances in the male with incidentally the anatomy, physiology and pathology of those diseases of *some* of the organs connected therewith For specialists the book will be an instructive one, and the latest illustrations giving all the operative methods for the treatment of vesiculitis will be very interesting The history and methods of incisions for operations on the vesiculæ seminales are given, but all those familiar with the literature of the subject, and especially with the work of Monod and Terrillon, on diseases of the testicle, published in Paris in 1889, will see that comparatively little on the general subject with the exception of the operative measures named, has been added The diseases of the testicle are hardly mentioned in the book, and then only *incidentally* We trust that should the work pass to a future addition, the author will change the name, or have it include the diseases of the testicle As a monogram on seminal vesiculitis, it is without doubt the most comprehensive of any

Hare's Text-Book of Practical Therapeutics A Text-Book of Practical Therapeutics, With Especial Reference to the Application of Remedial Measures to Disease and their Employment upon a Rational Basis By Hobart Amory Hare, M D Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia With special chapters by Drs G E de Schweinitz, Edward Martin and Barton C Hirst New (fifth) edition, thoroughly revised In one octavo volume of 740 pages Cloth, $3 75, leather, $4 75 Philadelphia Lea Brothers & Co, Publishers 1895

As this book has now passed to its fifth edition, it needs no special commendation on the part of the writer of this notice The revision has brought the book down to date Each article has been revised and the antitoxin treatment of diphtheria has been introduced The author mentions with approval that the 'gross percentage of mortality without taking favorable cases alone and including operative cases, ranges from 5 to 23 per cent as against the ordinary mortality of about 50 per cent The dose of the antitoxin serum is to be judged by its known strength and power, when conferring immunity, by the severity of the disease and the susceptibility of the patient The present common dose of the antitoxin serum of Behring and Parke, Davis & Co, is 5 to 10 cubic centimeters, while that of the strongest serum is much less One valuable feature of this book is the posologic table at the end, where doses of all the medicines are given in the metric system, as well as in the old British apothecary system

Some of the Physiologic Factors of the Neuroses of Childhood By B K Ratchford M D 8vo, pp 122 Cincinnati Robert Clarke Co 1895

This little book is a republication of a series of papers first published in the *Archives of Pediatrics*, and for the benefit of those of our readers who have not seen that publication we give the following general synopsis of the contents Chapter I, normal Function of Nerve Cells, II Physiologic Peculiarities of the Nervous System of Infancy from Childhood, III, Fever and Variable Temperatures of Childhood, IV, Heat Dissipating Mechanism, V, Autogenetic and Bacterial Toxins, VI, Venous Condition of the Blood, VII, Impoverished Condition *of the Blood*, VIII, *Reflex Irritation, and* IX, Excessive Nerve Activity

The author uses the term, "neuroses of childhood," to cover all local and general nervous disorders which do not have any known pathologic lesions of the nervous system It is thus seen that the title of the book is more comprehensive than its style and general make up would seem to indicate The papers contain the result of much original research *The chapter on auto-intoxication* is alone worth the price of the volume

Charaka Samhita Translated into English Published by Avinash Chandra Kaviratna Calcutta 1895 Part XIII

The thirteenth fasciculus of this interesting work has reached us, and on examination we find it completes the twelve groups of food and drinks Lesson XXVIII sets forth very quaintly the difference between men that are wise and *those that are ignorant and foolish* Lesson XXIX gives some curious observations on quacks ' Bad physicians or killers of life and helpers of disease" The good physician is thus described by the illustrious Son of Atri "Those that are well born of clear understanding, possessed of experience, skillful, of pure behavior, possessed of mastery over their hands, with souls under thorough control, equipt with every necessary object, with every sense in order, capable of reading the disposition of others, furnished with knowledge of results (processes operations, drugs, etc) are said to be saviors of life and destroyers of diseases"

Black on the Urine The Urine in Health and Disease, and Urinary Analysis Physiologically and Pathologically Considered By D Campbell Black M D, L R C S, Professor of Physiology, Anderson College Medical School *In one 12mo volume of 256 pages, with 73 engravings* Cloth, $2 75 Philadelphia Lea Brothers & Co, Publishers 1895

This book is an English printed one, for the use of students It is very condensed, concise, well illustrated, and will be found extremely useful for those who wish to have in a small compass a recent work on the science of urology It has been carefully brought down to date and will be found a valuable book of reference on the subject Practitioners will find it desirable to have a book handy for reference in the examination of specimens The only defect in it, so far as our observation has extended, is that too little attention has been paid to the examination of urine for bacteria The bacillus tuberculosis and bacillus ureæ are the only ones mentioned, and no specific directions for tests are given in the book, which we take to be a defect of omission, as in an authoritative work of this kind everything relating to the *subject should be set forth*

Manual of Organic Materia Medica, Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms, for the use of Students Druggists Pharmacists and Physicians By John M Maisch, Ph.M, Ph D, etc Sixth edition, revised by Henry C C Maisch, Ph G Ph D 8vo, pp 526 Philadelphia Lea Bros & Co 1895

This, as its name implies, is a *manual or hand-book of* materia medica, adapted to the use of medical students and students of pharmacy The new Pharmacopœia has been adhered to, and the doses are given in metric terms Although the matter in the present volume has been increased by slight enlargements of the pages and condensation, the bulk of the volume is not materially augmented. It will as heretofore, without doubt, continue to be a favorite with students

A Manual of Obstetrics By A F A King, A M, M D, etc, Sixth edition, 221 illustrations, 8vo, 533 pages Philadelphia Lea Bros & Co 1895

This is one of the most popular treatises on obstetrics that has been issued for some years, a fact which has been attested by its having passed its sixth edition We trust, however, that in the next edition our friend will recast the chapter on inflammation of the breast, especially the section thereof which refers to the causes of mammary inflammation, in order that the bacteriology of the subject may be brought to conform to modern views A similar criticism might, without being hypercritical, be extended to the entire Chapter xxxiv, on puerperal septicemia, septic and "non-septic" puerperal inflammations, etc

PUBLIC HEALTH

Smoke Abatement —It will not be very encouraging to the authorities of the many towns and cities in this country who are striving to abate the "smoke nuisance" to read the latest utterance of Sir Douglas Galton, the eminent President of the British Association for the Advancement of Science, on the subject It occurs in his Presidential Address, at the opening of the recent meeting of the Association on the 11th ult After pointing out that much may be done by care in firing, by using smokeless coal and by washing the soot out of the products of combustion, he intimates that in the general use of electricity lies the only adequate remedy and that this is too costly where it must be generated by the use of coal "I can conceive, however, that our descendants may learn so to utilize electricity that they in some future century [!] may be enabled by its means to avoid the smoke in their towns"

"Quis Custodiet Ipsos Custodes" Again —What can be expected of the ignorant and uneducated when those who are to guard their health and cure their sickness openly violate the simplest hygienic precautions? Professor Virchow, Rector of the University of Berlin, declares that in spite of the large number of suitable receptacles for saliva, placed by his order at all convenient places in the university building, the students continue, as in the past, to defile the floors of the halls and rooms that they frequent with their expectorations It is now suggested that a rule be adopted, imposing a penalty for each offense against this common requirement of decency and sanitation, similar to that decreed by the municipality of Sydney in New South Wales, where a fine of $5 is levied upon every person detected spitting in public buildings, vehicles or streets

Diphtheria Antitoxin Statistics in Russia —Dr Zabolotnui has furnished the following figures of the results of the antitoxin treatment of diphtheria in the district of Podolia, which have been reprinted from a local journal of the district in the *Meditzinskoe Obozrienie* In 109 cases proved bacteriologically to be true diphtheria, injections of antidiphtheritic serum were employed The number of deaths was 14, the percentage death rate was therefore 12 8 Previously, under the old forms of treatment, the death rate had been 48 per cent Prophylactic injections were given to 228 healthy children, stated to be members of families in which cases of diphtheria had occurred None of these persons contracted the disease Dr Zabolotnui himself underwent the treatment for an attack of diphtheria, and describes graphically the rapid subjective improvement after the first injection, the disappearance of headache and of the apathetic state into which he had fallen, with corresponding rise in spirits and improvement in all the specific symptoms The temperature fell from 39 6 C to normal after the first injection

Suicide in European Cities —Recent vital statistics show the following numbers of cases of suicide per 10,000 of population Munich, 1 93, Berlin, 2 98, Vienna, 3 2, Brussels, 3 29, Paris, 3 6, Breslau, 3 91 The Vienna correspondent of *The Lancet* furnishes some interesting data concerning suicides in that city In every 100 cases, 77 were men and 23 women Adolescents appear to have even more frequent recourse to this method of terminating their real or supposed miseries, the highest rate being registered at the age of 16 to 25 years Among 100 suicides, 32 5 ended their days by hanging, 23 5 by pistol shots, 22 4 by poisoning, 5 8 by drowning With respect to the poisons, cyanid of potassium was resorted to in 12 7 of the cases, caustic lye in 22 7, phosphorus in 26 1, and sulphuric acid in 7 2 As for seasonal distribution the proportions were in January, 8 5 per cent, in February, 7 6 per cent, in March, 8 9 per cent, in April, 9 1 per cent, in May, 10 5 per cent, in June, 8 7 per cent, in July, 8 1 per cent, in August, 7 2 per cent, in September, 7 4 per cent, in October, 8 3 per cent, in November, 7 8 per cent, and in December, 7 9 per cent

School Diffusion of Diphtheria —Although there was some increase of diphtheria noted throughout the country toward the close of August, the weekly mortality reports for September indicate a much greater prevalence of the disease since school has "taken up" In New York city this increase is so great that the antitoxin supply is inadequate and orders for the serum from other communities have been refused In Chicago the number of deaths during the month has increased fully one-third over that of August In a recent report to the London County Council, Shirley Murphy shows in a very striking manner the relation of the autumnal increase of diphtheria to the school population Taking three periods of four weeks before vacation, the four vacation weeks and the four weeks after vacation, he finds a remarkable reduction in the vacation period from the ante-vacation period, followed by a still more remarkable increase in the post-vacation period In 1892 this reduction was 3 per cent and in 1893 it was 27 per cent The increase in 1892 was 29 cent and in 1893 it was 81 per cent It is to be especially noted that there is no such constant and marked relation discoverable in other age periods, but that it is confined to children of the elementary school age—in that country between 3 and 13 years There is, of course, some decrease and some increase at other ages, but this may be fairly attributed to lesser or greater infection derived from and secondary to the school cases

Returns of Sanitation —At the recent meeting of the Sanitary Association of Scotland held in Greenock, the medical officer of health of that town presented some statistics which speak eloquently of the value of sanitation and of the returns from sanitary expenditure Prior to 1860 the town had been repeatedly scourged by outbreaks of the contagious and infectious diseases—the death rate for the twelve years 1843–1854 inclusive being 35 5 per 1000 of population, rising to 61 3 in 1847 and to 64 2 in 1849 The cholera epidemic of this latter year caused an inspector to be sent to the town by the General Board of Health in London, who pointed out glaring defects in the main drainage and other matters This was followed by radical improvements of the health administration, further pollution of the harbor was remedied by the construction of a complete system of main sewers, the water supply was improved at a cost of nearly two million dollars, another million was expended in alterations under the Artizan Dwellings Act, numbers of dilapidated dwellings were destroyed, new streets were opened, letting in sun and air, and sanitary reforms were carried out in other directions The increased working force of the population, its saving of doctors' bills, medicines, nursing, wasted time, suffering, funeral expenses, etc, may be inferred from the following figures from 1865 to 1869 the death rate was 32 46 per 1000 of population from 1870 to 1874 it was 29, from 1875 to 1879 it was 23 09, from 1880 to 1884 it was 22 13 from 1885 to 1889 it was 18.28 What is true of Greenock is true of every other place where systematic, organized sanitary effort is made As Professor Hay said during the Congress "With a rapidly growing knowledge of the laws of health, derived from extended experience and the laborious observations and investigations of many workers, in recent years we have been making a freer and more intelligent use of the powers conferred by the Legislature Our forces in the war against disease and death are being marshalled and outlined with something like military order and precision It were an easy task if time permitted, to cite instance after instance of victorious progress" And for this country—*Let us have a Department of Public Health!*

Longevity of the Typhoid Bacillus—The present serious increase of typhoid fever in Chicago, as well as its epidemic prevalence elsewhere, gives especial interest to the recently published studies of Prof Edwin O Jordan, Ph D of the University of Chicago, on the conditions affecting the behavior of the typhoid bacillus in water[1] Professor Jordan has already indicated in this JOURNAL[2] some of the difficulties that environ the identification of this organism—difficulties which, as he has pointed out, make it imperative to record the source, age and character of the culture used, and in the present elaborate paper he gives additional reasons for vigorous precaution in this particular Among the other practical points with which the paper abounds, a large number of experiments, conducted with painstaking thoroughness, show conclusively that the bacilli invariably live longest in waters containing the largest amounts of organic nitrogen It is a noteworthy fact that this holds true even when no appreciable multiplication occurs This latter interesting circumstance is open to the interpretation either that the lives of individual bacilli are conserved by the presence of organic matter, which acts as a kind of "elixir of life," or that the more hardy bacilli are able to multiply for one or two generations on the slight amount of peptone supplied them, a multiplication that however, is masked by the mortality occurring among their less resistant companions For obvious reasons the second explanation seems the more plausible Briefly stated, the results of the experiments made and recorded by Professor Jordan are as follows

1 The age of the typhoid stock influences greatly the life of the bacilli introduced into water, a freshly isolated stock possessing distinctly greater vitality than one that has been under cultivation for some months

2 The typhoid bacillus when introduced with proper precautions into sterilized Lake Michigan water does not multiply but may, under certain conditions, maintain its vitality for upward of ninety-three days

3 The colon bacillus, on the contrary, under similar conditions undergoes rapid multiplication and may remain alive for upward of 262 days

4 In redistilled water the typhoid bacillus perishes much more speedily than in the water of the lake

5 The quantity of organic matter (peptone) in redistilled water influences fundamentally the life of the typhoid bacillus, so small an increment as 0 0126 organic nitrogen (parts per 100,000) causing a perceptible lengthening of life

6 In sterilized lake water the addition of a still smaller quantity of organic nitrogen—0 0012—affects the longevity of the typhoid bacilli introduced

Health Reports—The following health reports have been received by the Supervising Surgeon-General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Louisiana New Orleans, September 14 to 21, 12 cases
Michigan Detroit, Battle Creek, Battle Creek Township, Marshall Township, Bedford Township, smallpox reported present September 25
Pennsylvania Philadelphia, September 14 to 21, 1 case
Tennessee Memphis, September 21 to 28, 3 cases
West Virginia Wheeling, September 15 to 28, 1 death

SMALLPOX—FOREIGN

Buda-Pesth September 2 to 9, 1 case
Dublin September 7 to 14 9 cases, 1 death
London, Eng September 7 to 14, 42 cases, 2 deaths
Naples September 7 to 14, 2 cases, 2 deaths
Nogales September 14 to 21, 1 case
Odessa August 31 to September 7, 3 cases
Prague August 31 to September 7, 1 case
Rio de Janeiro August 17 to 31, 121 deaths
Rotterdam September 7 to 14 2 cases, 1 death
Rouen August 1 to 31, 10 cases 6 deaths
St Petersburg August 24 to September 7, 7 cases, 1 death
Trieste August 31 to September 7, 1 case
Warsaw August 31 to September 7, 1 death

CHOLERA

France Cognac, August 31 to September 6, 1 case, 1 death, Paris, August 18 to 31, 6 cases[1]
China Hong Kong, August 10 to 24, 7 deaths
Japan Nagasaki, August 23 to 30, 64 cases, 51 deaths, Osaka and Hiogo, August 17 to 31, 346 cases, 264 deaths
India Madras, August 17 to 23, 3 deaths
Austria Hungary Galicia, August 28 to September 2, 9 cases, 2 deaths
Russia Volhynia, July 7 to 12, 49 cases, 13 deaths, July 21 to 27, 222 cases, 72 deaths, July 28 to August 3, 406 cases, 168 deaths, August 4 to 10, 1,004 cases, 322 deaths, August 10 to 17, 2,025 cases, 718 deaths, Warsaw, August 26, 1 case, Ostrog, Kremenetz, Sarpaw, Starokoustantinow, Nowogrodwalynski, Dubno cholera reported present August 11 to 17
Turkey Hudavendkjar (vilayet), August 18 to 25, 82 cases 56 deaths, Konia (vilayet), July 25 to August 25, 5 cases, 4 deaths, Adana (vilayet) August 12 to 24 34 cases, 17 deaths, Aleppo (vilayet), August 6 to 20, 191 cases, 98 deaths, Diabekir (vilayet), August 12 to 24, 184 cases, 223 deaths, Broussa, August 26 to 19, 47 cases, 19 deaths

YELLOW FEVER

Cuba Havana, September 12 to 19, 120 cases,[2] 39 deaths, Sagua la Grande, September 7 to 14, 1 case
Brazil Rio de Janeiro, August 17 to 31, 12 deaths
Mexico Vera Cruz, September, 12 to 19, 5 deaths

NECROLOGY

HENRI ADOLF BARDELEBEN, M D of Berlin, Germany, aged 77 years He was born in Frankfort on-Oder, and studied medicine in Berlin Heidelberg and Paris He became professor in the University at Giessen in 1848, subsequently leaving to take the chair of surgery in the University of Griefswald In 1868 he became a director of surgical clinics in the Royal Hospital of Charity at Berlin He was chief of the medical and surgical staffs in the wars of 1866 and 1870, and was associated with Professors Virchow and Muller in several medical works——J W McAlister, M.D of Albany, Miss September 17——E W Burnette M D, of New York, September 20 aged 52——H N Hollifield, M D, of Sandersville, Ga, September 23, aged 63——Charles Bain, M D, of Murphysboro, Ill, September 27, aged 70

MISCELLANY

The American Public Health Association, have elected Dr Eduardo Liceaga, of Mexico, Mex, President of the Association for the ensuing year The next meeting will be held in Buffalo N Y

The Long Island College Hospital—According to the *Brooklyn Medical Journal* for September, this institution has received a handsome gift from the widow of a recently deceased regent, Mr Henry D Polhemus That gentleman, during his lifetime, had been a frequent contributor to the support of the school He, with others, had more than once come to the front and saved the school from extinction His widow now purposes to construct a memorial which will bear in perpetuity her late husband's name, and which will facilitate the training of students in an institution with which he was closely identified for so many years The building which Mrs Polhemus will erect, and when completed will present to the Long Island College Hospital, will be both a dispensary and a medical college combined It will be situated directly opposite the present college structure The plans are now being prepared by the architect, and it is expected that it will be ready for occupancy in September, 1896, at the time of the opening of the college, and happily coincident with the beginning of the graded system of instruction which the college has adopted The estimated cost of the property and building is $250,000, and it is the purpose of Mrs Polhemus to endow the memorial for its permanent maintenance with an additional sum of $250,000

[2] Largest mortality from yellow fever in Havana since 1884

New Anatomy Law in Wisconsin —Section 1437, of chapter 58, of the annotated statutes of Wisconsin, was amended by the last Legislature so that every public officer having charge of the body of any deceased person, required to be buried at the public expense, not merely "may," but "shall without charge," deliver such body to that member or agent of the State or any county medical society, or of any legally organized medical college who shall first present to him an order therefor, signed by the president or secretary thereof, "stating" that such body will be used only for the promotion of anatomic science within the State, and that the remains shall be afterward decently buried without public charge But, as heretofore, no body of any person who in his last sickness requests to be buried, or of any stranger or traveler who shall have suddenly died, shall be so disposed of And no person so having charge of any such body, it is added, shall sell or deliver the same to any one to be used for scientific or any other purposes outside of the State of Wisconsin Any officer or other person violating any of the provisions of this act shall be liable to the person, society or corporation aggrieved in the sum of $50 damages, to be recovered in an action therefor

The Red Cross Society of Japan —The Japanese have grasped the humane principles and practice of the Red Cross with wonderful avidity Miss Clara Barton, President of the American Red Cross, says "Japan is one of the strongest Red Cross nations in the treaty since 1886, in some respects the most advanced Red Cross country in the world, with its every right protected, its Emperor and Empress not only at the head officially, but actively at the head of its national society, directing all its hospital and relief work, and challenging the world in its efficacious methods" Its first active service of importance was during the insurrection of 1877, which lasted eight months It was then known as the "Hakuaisaka," or Society of Benevolence, and the society was not affiliated with the great international movement When "The Red Cross Society of Japan" was finally formed, the Emperor and Empress granted it an annual subsidy of 5,000 yen (a yen is 99 5 cents) and large money and land gifts for the erection of hospitals Princess Arisugawa, a royal scion, Princess Komatsu, with several other princesses, and a large number of ladies of distinguished families, meanwhile formed a band of nurses After that point was reached the development was rapid, and at the present time the total membership in Japan is probably not less than 100,000 souls Almost every prominent officer is connected with it Altogether the society has received in gifts from the crown between 200,000 and 300,000 yen for the purpose of increasing its efficiency

Amblyopia in Recruits —The seventh annual session of the Ophthalmological Society of the Netherlands was held at The Hague early in June Dr Straub presented a report, on a series of examinations of eyes of young men, entitled "Amblyopia in Eyes of Normal Appearance" He stated that "he had examined 350 young men of almost the same age, all of whom had a visual acuity less than that required for military service, without its being possible with the ophthalmoscope to find disturbances in the media or alterations in the deep membranes On eliminating those whose vision was not less than the average vision proper to their degree of refraction, and hysterical cases and cases of simulation, there remained 171 cases To be absolutely sure of not figuring on cases in which errors of refraction could play any part, sixty-five of these were excluded The 106 remaining cases were divided into isometropes and anisometropes Each group thus obtained was divided according as only one or both eyes were amblyopic, and the latter group was again divided into two parts those with binocular vision, and those without it The figures thus obtained seemed to prove that neither anisometropia nor absence of binocular vision can account for the amblyopia The existence of an amblyopia, in the sense of Schwiegger, must, then, be admitted

"Goldzieher attributes this amblyopia to traumatisms of the eye at birth Noumhoff, who has examined the eyes of fifty children who died during delivery, has found hemorrhages of the choroid in half of the cases It is very probable that congenital amblyopia is caused by very small ruptures of the central portions of the retina, occurring during labor"

An Ancient Fee-Bill.—In a late number of *Le Progrès Medicale* appears the price list charged by the executioners of ancient Paris for their services to the State, in taking life, or cutting off an organ, of convicted culprits The writer of the article has unfortunately omitted to affix the probable date of the schedule of prices, and he does not inform us when the polite Parisians ceased to deal out the terrible punishments of "those former days" There is one item, "the Gehenna torture," that is very suggestive of heat and suffocation, but the explanatory foot note is not supplied The executioner seems to have had two different prices for quartering a man

AN EXECUTIONER'S PRICE LIST

	Livres
To boiling a malefactor in oil	48
To quartering him while alive	30
To affording a criminal passage from life to death by the sword	20
To breaking the body on the wheel	10
To fixing his head upon a pole	10
To cutting a man into four pieces	36
To hanging a culprit	20
To enshrouding the corpse	2
To impaling a living man	24
To burning a sorceress alive	28
To flaying a living man	28
To drowning a child murderess in a sack	24
To burying a suicide at cross-roads	20
To applying the torture	4
To applying the thumbscrew	2
To applying the buskins	4
To administering the Gehenna torture	10
To putting a person in the pillory	2
To flogging	4
To branding with a hot iron	10
To cutting off the nose, the ears or the tongue	10

Statement of Facts to be Covered by Medical Certificate of Lunacy —The Massachusetts Legislature has suggested a form for a medical certificate of lunacy, covering 1, sex, age, nativity, color, occupation, whether single, married, or widowed 2, number of previous attacks, when present attack began [If the patient has ever been an inmate of an institution for the insane, when, where, and for what length of time, and whether discharged, recovered or otherwise] 3, was present attack gradual or sudden in its onset? 4, what is the bodily condition of the patient? 5, has the patient been physically injured? If so, when and to what extent? 6, is the patient subject to epilepsy? 7, is the patient cleanly in dress and personal habits? 8, is the patient paralytic, violent, dangerous, destructive, excited or depressed, homicidal or suicidal? 9, what is the supposed cause of the patient's insanity? [State both the predisposing and exciting cause] 10, has the patient insane relatives, and if so state the degree of consanguinity, and whether paternal or maternal? 11, what are the patient's habits as to the use of liquor, tobacco, opium, chloral or other narcotic? Following this statement of facts, the examiner who makes certificate that the patient is insane, and a proper person for care and treatment in an institution for the insane, is required to state the facts on which he has formed his opinion —what the patient said to him, what the patient did in his presence, the patient's appearance and manner, other facts indicating insanity, including those communicated by others, and what, if any, change there has been in the patient's mental condition and bodily health.

Soloids for Antiseptic Uses.—Under the above style, a well-known London firm of manufacturing chemists has introduced three or more forms of antiseptic tablets for sanitary gynecologic and surgical purposes. One form is that of corrosive sublimate, with a sufficient quantity of an alkalin chlorid to prevent decomposition in hard water; one of these soloids dissolved in ten pints yields a solution sufficiently strong to destroy micrococci and bacilli, but this must be increased ten times—one soloid in one pint of water—for the purpose of destroying the spores of microörganisms referred to; and this is the strength usually employed in dealing with exposed surfaces, such as walls and floors of infected rooms, textile fabrics used in connection with patients, to purify the hands of operators in various surgical work, and for the proper cleansing of given skin areas whereon it is intended to make incisions. One of these soloids to a quart of water will suffice to secure an antiseptic solution suitable for sponges, instruments, etc. These soloids are colored in such a way as to make the resultant solution unlike any other liquid usually associated with the operating table or the sick room. A second variety of soloid is that of a combination of the iodids of mercury and potassium. It is claimed that this soloid possesses twice the bactericidal strength of the sublimate salt, does not precipitate albumin, is much less toxic and less liable to cause irritation. Each soloid contains 8.75 of the double salt, so that one dissolved in a pint of water gives a solution of 1 to 1,000 for use in the treatment of newly exposed surfaces in surgical operations, and to insure the perfect asepsis of the hands and instruments. A third preparation is called the "Local Government Board" soloid, because it is made up in such a manner that two of these soloids will afford a solution of the strength and character recommended by the Local Government Board Memorandum of 1892. These L. G. B. soloids are highly convenient, and rapidly soluble in ordinary well water, and their peculiar but perfectly harmless coloration and terebinthine odor are safeguards against poisoning by accident or mistake. White fabrics soaked in the soloid solution are stained a very light blue, but this color is nearly discharged by merely rinsing the fabric in cold water, so that no damage is caused to linen, etc., with which it may come in contact. The prices of these antiseptic tablets per hundred, vary from 50 cents to $1.45, "on the other side."

Abandonment of Fort Hancock, Texas.—This military post has apparently fulfilled the purpose for which it was established, for, by direction of the Secretary of War, Sept. 6, 1895, it will be discontinued and the public lands on which it is situated will be turned over to the Department of the Interior. This post was established in 1872 as an outpost on the Rio Grande, fifty-two miles southeast of the town of El Paso. At first it was called Camp Rice, and was looked upon as of so temporary a character that no mention was made of it in the Barrack Circular published by the Surgeon-General's office in 1875. At that time Dr. J. J. Hammond gave advice as follows to medical officers who were ordered to duty in the Department of Texas: "The service is essentially frontier service, including garrison duty, escort duty and duty with scouting parties, and medical officers coming here for a tour of duty should provide themselves accordingly. There is little time or opportunity for the enjoyment of luxuries. There is no society outside of the garrison, and this gives an opportunity to officers to avoid living beyond their means. Letter paper, envelopes and pens should be brought along; slat cots with legs to fold up, for bedsteads and lounges, and hair mattresses and pillows are most suitable. Wash stands and ottomans can be extemporized from boxes and barrels. Chairs not glued together, or camp stools are the best as being less costly to transport. Bare floors in summer, and matting or oil cloths in winter, are more healthy and more appropriate than carpets, etc."

All this became changed with the opening of the Southern Pacific Railroad. Fort Hancock became a permanent post built of brick, raised two feet from the surface on stone foundations. Although 2,500 feet above the sea level the site was a flat of sandy loam, covered with chapparal and liable to overflow because only a few feet higher than the banks of the Rio Grande. The barracks was a long two-storied building, roofed, like all the other buildings at the post, with shingles, and with a wide veranda along its sides. The lower story contained the orderly room, store room, library, kitchen and dining room, baths and tailor's shop; the upper, the dormitories, well lighted and with ridge ventilation. The officers' headquarters were commodious brick cottages. The hospital consisted of one ward of eight beds, with doctor's office, dispensary, steward's room, attendant's room and baths in the main building, and kitchen, dining room and store rooms in a frame addition. The water supply was pumped from a well near the bank of the river into tanks, one of which was used for sedimentation, a second was used as a distributing reservoir, and a third with a higher water level was kept as a reserve in case of fire. There were three-fourth inch pipes for service in all the buildings and nine hydrants at suitable points for the fire service. Waste water was carried into cesspools; excreta disposed of by the dry earth system in galvanized iron boxes, and garbage carted to a dumping ground a mile distant from the post. During the day in summer the temperature ranges from 95 degrees F., to over 100 degrees, but the nights are generally cool and comfortable. The mean temperature of the winter months is about 40 degrees, but sudden changes are then more likely to occur than during the summer months. Fogs are of rare occurrence, but high winds and dust so frequently prevail as to be a cause of nasal and bronchial catarrh. Many cases of malarial fever have been reported from this post, but in most of them the disease was probably contracted when the troops were on scouting duty in other parts of the Department.

Electrolysis in Detachment of the Retina.—The *Annales d'Oculistique* for July contains a report by Dr. Terson, of Toulouse, of twelve cases of the above treatment. The cases were all serious and some of them desperate in their gravity. One of these resulted in a recovery that has lasted nine months; there was improvement in five cases continuing from two to nine months; there were two with negative results and in one case the trouble was aggravated. The report of the successful case is given, in part, below.

"A female 34 years of age, a seamstress, came to the ophthalmologic clinic of the Hôtel-Dieu at Toulouse, on August 6, 1894, stating that eight days before she had lost the sight of her right eye. She had at first noticed a black mass which prevented vision on the nasal side, and then in a few hours the curtain advanced to the middle of the eye, and little by little invaded the entire eye, so that on the next day she could only distinguish light from darkness. It was in this condition that I saw her. She had always been myopic, and had always seen less with the right eye than with the left, of which she did not complain. On inspection I noticed that the anterior chamber was of abnormal depth, the pupil reflex was very weak, and the iris trembled slightly. The fundus of the eye had a dirty, yellowish appearance, like that seen at the commencement of infection. The tension was manifestly diminished. On ophthalmoscope examination, I found an extensive sac-shaped detachment, which included more than a third of the retina. The disc was scarcely distinguishable on account of a generalized cloudiness of the vitreous humor. The left eye was myopic 7 dioptres with weak vision.

"Although considering this condition as desperate, I submitted the patient to electrolysis, and applied a current of 5½ milliampères for one minute. No reaction occurred. Forty eight hours after, I had the patient get up to make an ophthalmosopic examination. The removal of the bandage was a revelation. The vitreous, which had regained its transparency, enabled me to see atrophic disseminated choroidal plaques and a macular lesion. There was no longer a trace of detachment of the retina. The anterior chamber had become more shallow, and the pupil reflex was normal. Wishing to follow the experiment to the end, I did not prescribe any further treatment. On the sixth day there was no trace of detachment. The external appearance of the president and the secretary of each school, which shall embrace certain questions specifically set forth

The rules of the board are specifically directed against any medical school that holds preliminary examinations for its incoming students, and its strict application of them will exclude the graduates of nearly all medical schools from practice in Missouri, save after an examination approved by the board Granting that the board is actuated by a praiseworthy desire to elevate the standard of medical education and practice, it would seem that these efforts to obtain that end were at least ill-considered In the first place, there is no uniformity in the attainments of those who may possess high school diplomas, in the second place, no difference is made between the high school diploma and the diploma from a college In all reason, a certificate of entrance to a college should be equivalent to a high school diploma In the third place, the exaction of a teacher's first-grade certificate is evidently the result of ignorance of the common requirements for such a certificate For in many States the applicant for such a certificate must give evidence of having been a teacher for three years The better colleges of the city are in full sympathy with the board in their effort to raise the standard of medical education, but the faculties will doubtless oppose the continuance of rules which will ultimately give them only local students This year the regulations of the board have injured only the weaker colleges of the city and State

THE MARION-SIMS COLLEGE OF MEDICINE opened on the 24th ult with a class of 325

HOSPITAL ABUSES —During the week, investigation has shown that there have been gross abuses at the Female Hospital during the past year The exhuming of several coffins shows that an unlawful traffic in bodies was carried on at the hospital

Washington Notes

HEALTH OF THE DISTRICT —The report of the Health Officer for the week ended September 21, is as follows number of deaths white, 52, colored, 61, total, 113 Death rate per 1000 per annum, white, 14 41, colored, 36 08, total, 21 32 Death rate per 1,000 per annum for corresponding week last year, 20 76 There was a decrease in the death rate last week The deaths reported to the Health Department numbered 113 as against 122 in the week before The annual rate fell from 23 02 to 21 32 As compared with the last report the mortality from diarrheal diseases declined from twenty-one to twelve, that of infants under 5 years old from forty-nine to thirty-eight, and that from typhoid fever from twenty-one to thirteen The investigation into the cause or causes of the prevalence of this latter malady in the District, as referred to in last week's report, is still in progress, with a view to the adoption of such remedial measures as possible Aside from this disease the city is comparatively healthy, being quite free from contagious affections and malarial troubles, with a continuously decreasing mortality from summer complaints

MEDICAL DEPARTMENT OF GEORGETOWN UNIVERSITY —The opening exercises of the Georgetown Medical School took place on September 30 Surgeon-General George M Sternberg, U S A, delivered the inaugural address

MEDICAL DEPARTMENT OF THE COLUMBIAN UNIVERSITY —The opening exercises of the Columbian Medical School took place on October 1 The address was delivered by Dr W W Johnston

MEDICAL ASSOCIATION OF THE DISTRICT OF COLUMBIA —The regular meeting of the Association was held on October 1 The election of new members was the principal business

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA —The regular weekly meeting of the society was held October 2 Dr Wm P Carr delivered an essay on "The Nature and Treatment of Tumors of the Breasts"

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY —The annual meeting of the society took place October 4 The President, Dr H D Fry, delivered the Presidential Address The annual banquet will take place on October 18

DR S C BUSEY has almost entirely recovered from his late accident

THE EASTERN DISPENSARY —A committee representing the dispensary called upon the Commissioners during the week, for the purpose of getting the latter to include in their estimates to Congress an item of $10,000 for the purchase of the building and ground occupied by the dispensary on Delaware Avenue

GARBAGE DISPOSAL —The crematories for the disposal of garbage will, in all probability, be completed on or about January 1 The contractors for the work have agreed to build the plant and submit it to test for three months without cost to the District If they are satisfactory they will be accepted, if not, they are to be removed at the expense of the contractors

THE COLUMBIAN UNIVERSITY'S NEW PRESIDENT —The new President of the Columbian University, Dr B L Whitman, has arrived and formally entered upon his new duties The President is particularly interested in the Medical Department, and his connection with the school will in itself greatly increase the number of students

THE PUBLIC SERVICES

The Retirement of Medical Director Gihon

MEDICAL DIRECTOR ALBERT LEARY GIHON U S Navy, was retired September 28 He was born in Pennsylvania in 1833, and the naval record of this officer is unsurpassed by any member of his corps His phenomenal public services entitle him to public recognition, and his long and faithful service in our ASSOCIATION has endeared him to its members The members will be pleased to know that DOCTOR GIHON will be even more active as a medical writer, now that he is free from official care and the readers of the JOURNAL are promised occasional articles from his forceful pen Few write with more elegance and none from broader sources of information

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from September 21 1895 to September 27, 1895

Major Joseph B Girard Surgeon (Presidio of San Francisco, Cal) is granted leave of absence for one month, to take effect about the 5th proximo

Major James C Worthington, Surgeon, is granted leave of absence for three months, on surgeon's certificate of disability

A board of medical officers, to consist of Col Charles H Alden, Asst Surgeon General, Lieut Col William H Forwood, Deputy Surgeon General Lieut Col David L Huntington, Deputy Surgeon General Major Charles Smart, Surgeon Major Walter Reed, Surgeon is constituted to meet at the Army Medical Museum Building in Washington D C, on Tuesday, Oct 1 1895, at 10 o'clock A M, for the examination of candidates for admission to the Medical Corps of the Army

Major Henry Lippincott, Surgeon is relieved from duty at Ft Adams, R I, and ordered to Ft Sheridan, Ill, for duty relieving Major Alfred C Girard, Surgeon Major Girard, on being thus relieved, is ordered to Ft Douglas, Utah, for duty, relieving Major Charles L. Heizmann, Surgeon Major Heizmann, on being thus relieved, is ordered to Ft Adams, R I, for duty

Capt Richard W Johnson, Asst Surgeon, will be relieved from duty at Ft Huachuca, Ariz, upon the arrival there of Capt William J Wakeman, Asst Surgeon, and ordered to Ft Logan, Colo, for duty

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending September 28, 1895

Surgeon D Dickinson, detached from the "Minneapolis," and ordered to examination for promotion

Surgeon D N Bertolette, detached from the "Atlanta," to duty on the "Minneapolis"

ANTIPHTHISIN IN TUBERCULAR AFFECTIONS OF CHILDREN

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md, May 7 10, 1895

BY PROF EDWIN KLEBS M D

DIRECTOR OF THE LABORATORY FOR THE STUDY OF TUBERCULOSIS CONSULTING PHYSICIAN IN THE WINYAH SANITARIUM

ASHEVILLE N C

The therapeutic application of antiphthisin has thus far been limited to comparatively few practitioners, partly on account of limited production, and partly because the remedy was only furnished to such as gave us assurance that they would restrict its application to cases which were not too far advanced in the disease, and in which we could still hope for its beneficial effects

The reason for restriction is apparent by the well known fact that specific medication can only be fully effective, when it is applied to pure uncomplicated cases, to the exclusion of those in which other pathologic processes are also present

It would certainly be unreasonable to demand that this remedy which has a specific germicidal effect upon the tubercle bacillus only, shall also remove and cause the cure of pathologic changes, which result remotely from the primary cause and, more unreasonable still, that the remedy shall also favorably influence and cure complications which like infection with other pathogenic germs have no relation to tuberculosis at all, more, than that they may be associated in the same patient

In all such cases it is necessary to remove the complications by other treatment, either before or in conjunction with the application of the specific remedy, but the final results are determined by the importance and curability of such attending pathologic processes

We see thus, that the use of a specific germicidal remedy can only be fully effective when the disease is still uncomplicated by secondary degenerations, and is free from complications which, unfortunately are present in most cases of tubercular disease as they come under our notice, there are, however, not a few cases of purely tubercular affections in an early stage in which the results of specific medication are highly satisfactory In such cases I have every reason to believe that under proper use of the germicidal products obtainable from the bacillus of tuberculosis, a cure will result almost without exception For these as in all other therapeutic efforts the only unavoidable condition is that the organism itself shall still have the power to use and appropriate the introduced curative substance, for under no circumstances can we otherwise conceive the cure of disease, than that the living organism must, itself, take an active part in its removal

Since the living organism can not by any means be compared with dead substances or matter which we can disinfect, regardless of the changes which occur within it, we have little to hope from chemic or physical means in the form of high temperatures, acids, alkalies, etc, and all hopes in this direction have thus far been changed to disappointment, their action having invariably been found a distinctly local one, beyond their direct application, they lose their intended effectiveness in the living organism by their undergoing insoluble or inert chemic combinations, by saturation or by diffusion

With specific germicidal agents we have become acquainted only within more recent years, and, so far, they all are products of specific germs and not subject to changes such as we have learned do occur in the chemic and physical agents referred to, on the contrary, we observe them to reach the diseased structures directly and uninjured, and to become effective there

This fact is not explained by assuming with Robert Koch, a peculiar affinity or attraction, the same as was taught by older schools of medicine to be the action of drug remedies, but by the imbibing and transportation of these curative substances through the agency of leucocytes

For this, speak the penetration of leucocytes into the tubercular tissues and the production there of a substance which behaves peculiarly to certain anilin dyes, and the presence of which can only then be demonstrated when the specific curative substance has been introduced and has inaugurated the cure[1] With this occurrence we see the tubercle bacilli diminish and disappear, while within the coagulated protoplasm of tubercular cells, the nuclei appear again in their normal coloring properties

Upon the basis of such experimental observations, we can explain and understand why we are able to favorably influence specific pathologic changes within the living organisms with relatively small quantities of the specific remedy, and this I have shown to be the action of antiphthisin, while the crude tuberculin at the same time produces injurious effects, containing as it does, all the toxic substances produced by the tubercle bacilli in their cultures

It was necessary to preface this paper by the foregoing remarks in order to show the importance of proper selection of cases, and to also indicate the limitations of the remedy

Among the favorable uncomplicated tubercular processes are, in the first place,

THE TUBERCULAR AFFECTIONS OF CHILDHOOD

That the heretofore available therapeutic agents are insufficient for the treatment of scrofulosis is easily demonstrated, and I need only to point to the unsatisfactory results in the tubercular affections of bones and joints of children

---

Dr. Robert [illegible] Library
[illegible] Medical College
32584

The frequently observed cheesy myelitis of the long bones, although subjected to resection, is often followed by renewals of the process, which may finally compel ablation of the entire limb, and even with such radical operation, the life is not infrequently lost through extension of the disease to the pelvis, the spine or to internal organs

These cases are peculiar in the often observed long duration of the tubercular disease, although extensive destructive processes and extensive involvement of the glandular structures are present, without seriously damaging the general condition of the patient, a fact which makes them especially adapted for the treatment with antiphthisin

The danger of depending for the ultimate success upon the heretofore customary treatment is, however, shown, by the unexpected occurrence of inflammation and suppuration, by the advent of which the favorable time for specific medication has been lost, while the insufficiency of internal medication is also demonstrated, and we can not emphasize too much the fact, that scrofulous affections are primarily of a tubercular character, which so long as they remain purely tubercular, run their course without inflammatory complication

It is entirely the same with all other scrofulous and tubercular affections which, so long as inflammation and suppuration have not occurred, are all amenable to the antiphthisin treatment

What clinical results may be obtained will appear from a short resumé of cases treated by me, the number of which I regret is not as large as I could wish

In giving my experience, I divide my cases into several natural groups, the first of which I may call

THE LATENT TUBERCULOSIS OF CHILDHOOD

Of this group we find numerous examples in tubercular families The, at birth, apparently healthy children, show sooner or later a retardation in growth and that pale appearance, with thick upper lips, which may remind us of myxedema, and which on the whole we call the scrofulous diathesis In other cases the organism is simply retarded in its development, sometimes altogether, often only in length, the children remaining then short only, in other instances they grow rapidly in length, at the expense of corresponding breadth and fullness In any case, the absence of glandular swelling may simulate nutritive disturbances due to other causes which the physician hopes to overcome by dietetic and roborant treatment, and although at times successful, failure to correct the evil is by no means an exception, and the truly present latent tuberculosis is attested by the common saying that "such children sooner or later become tuberculous"

Just upon this point I desire to distinguish between the more modern views based upon bacteriologic research and the older theories based upon empirical observations only

We fortunately know now quite well, that tubercular infection does not necessarily cause stormy or violent symptoms, but that, on the contrary, it may remain latent for many years, and only show its presence by more or less nutritive disturbances which, instead of being predisposing conditions, are in fact the expression of the already present tubercular disease

If any experienced observer would still doubt this, he can certainly recall cases from his practice, in which the history shows such nutritive disturbances having been present in childhood, and in which during youth or early manhood a more rapidly developing tuberculosis occurred Neither will he have missed cases in which such latent tubercular affections have been approximately recovered from during childhood, and who, nevertheless subsequently, perhaps after considerable lapse of time, died of the disease Such cures when obtained through dietetic and climatic influences are, as a rule, not lasting, they do not assure against a later development, indeed, they may carry with them even a certain degree of danger, and I have repeatedly seen cases of young strong subjects in which suddenly, in connection with unusual or violent exertion, the acutest forms of pulmonary tuberculosis occurred In such cases we can then show anatomically a small, not previously diagnosed cavity from which dissemination of the tubercle bacilli took place as a consequence of such over-exertion

The practical physician may reply, that we certainly can not look upon all badly developed or poorly nourished children as tubercular, and this is not the case, neither is it necessary to here consider the other causes for nutritive deficiency in childhood But I consider it quite certain that by far the greatest number of such cases are subjects of latent tuberculosis, especially when no other good and sufficient cause is apparent The question is, How are they to be diagnosed, when the physical examination of organs is negative?

The answer is very simple, and it is a matter of surprise that the method of which we avail ourselves for recognition of latent animal tuberculosis has not been taken advantage of for diagnostic purposes in the human subject also

The greatest credit is due to certain American health authorities and statesmen to have first made practical use of a scientific fact in the systematic application of tuberculin for the recognition of latent tuberculosis in cattle, and history will recognize it equal in importance to the introduction of vaccination for smallpox

One might well ask why this simple and sure procedure has not found recognition and practice for the diagnosis of latent tubercular affections in the human subject? Whatever the answer may be, whether due to the objection of patients and parents, or to want on the part of the physician of proper insistence for such test, or whether the neglect lies in the newness of the procedure, as contrary to existing modes and habits, the members of the medical profession can not ignore and escape this issue, for the truth of its value is beyond doubt, and the test must be insisted upon in all cases where the diagnosis can not otherwise be sufficiently established

Among my cases of latent tuberculosis, I will call your attention to but few

Case 1—G B, a delicate girl aged 6 years, has been the subject of cough without any physical evidence on the part of the lungs, she was highly anemic, with deficient development of the osseous and muscular system, there was also slight swelling and tenderness of the cervical glands, râles could be shown in both apices, after the use of 20 cubic centimeters of antiphthisin, the child not only lost her cough entirely with disappearance of the râles, but she improved remarkably in general health and appearance, and has since remained entirely well

Case 2—N B, child 10 years old, tall and slender, the father died of tuberculosis There were only slight differences in the percussion note Very careful percussion showed, however, slight dullness in left apex posterior, on the right side posterior a little more marked relative dullness extended to the spine of the scapula In this locality inspiratory ronchi were also present and extended further downward, in several places, there was also blowing expiration, especially over right apex

After the use of 50 cubic centimeters of antiphthisin in thirty two days when she was discharged, the child gained two and one-half pounds, coughed only occasionally, no more dullness could be demonstrated, and since then has been entirely well

Case 3—O St, boy 13 years old,[2] suffered from asthmatic attacks for the last year, is imperfectly developed for his age, lips and nose thickened, has been mentally retarded also Hydrotherapy, climatic influence and local treatment of the nose have been of no benefit Weight 107 pounds, low temperatures, between 36 5 and 36 7 C, frequent coughing paroxysms, especially nights and with considerable dyspnea Physical examination showed moderate dullness over left lung, posterior to middle of scapula, and supraclavicular in front, also a small area of dullness at lower angle of right scapula, auscultation over left apex front and back gave blowing expiration and harsh inspiration, with here and there accompanying ronchi, also roughened respiration over the dull area at lower angle of right scapula At times expectoration, but none obtainable for examination, the expectoration disappearing entirely in the early part of the treatment After six weeks his weight had increased seven pounds, there was no cough no asthma and his general health was so completely restored, and his appearance so improved, that his mother upon her arrival could hardly recognize him to be the same child Physical examination showed nothing abnormal in his respiration, slight difference on percussion was still present

Under the influence of specific medication the tubercular intoxication apparently ceased, and the deficient nutrition gave place rapidly to normal conditions This case is the more interesting since long-continued climatic and hydropathic influences, as also the local treatment of the nose, were entirely without benefit

Since percussion differences were still existing, I did not consider this case as radically cured, but it is fair to presume, from the result obtained, that by timely repetition of the treatment further tubercular development can be prevented

In a second group of cases, I include

PURE NON COMPLICATED SCROFULOUS AFFECTIONS

Since the term, scrofulosis, is established, I think best to retain it, but I understand it to mean the specific pathologic processes occurring in childhood, produced by the bacillus of tuberculosis The form and composition of the cheesy deposits in scrofulosis is equally characteristic with those which we find in the so called "pearl disease" of cattle, and which are at times more or less calcareous, pediculated, or rich in granulation tissue resembling sarcoma

The scarcity of tubercle bacilli is usually common to both, which made the recognition of their etiologic identity exceedingly difficult Both are auspicious examples of the variation of pathologic processes produced by the same cause but upon a different soil

The scrofulous deposits, which I consider as the essentials of the process, are the product of the reaction, to the tubercle bacilli, on the part of the youthful organism, and may therefore be looked upon as a defense against the dissemination of the infecting germs If the defense is broken through, we see tubercular dissemination occur from the bronchial glands into the lungs or into the blood, from the cheesy nodules or deposits of nerve centers into the meninges, etc, showing that the tubercle bacilli must have been present from the beginning in these deposits How should they have found their way later into these non-vascular masses? for, indeed, we can no longer accept the theory of spontaneous generation

If further proof is, however, needed, we can also furnish it therapeutically, for if by any manner of procedure we succeed in destroying the tubercle bacilli, the cheesy deposits disappear According to the sentence "*Sublata causa, tollitur effectus*," must we conclude with mathematical certainty, that the tubercle bacilli are the cause of scrofulous new formations

Not infrequently we witness such a result through the inherent forces of the organism, when they are furthered upon Hippocratical principles, but in many cases such a natural recovery is impossible or only obtainable after irremovable and serious injury has occurred, of which the following case is a striking example

Case 4—S B, girl aged 16[3] was referred to me in Karlsruhe on account of a scrofulous eye affection Her development was retarded, corresponding to the age of 10 or 12 years, the insufficient development was the more striking on account of a coexisting hunchback, but her mental and sexual development was also retarded Menstruation had not yet occurred The eye affection which had long been unsuccessfully cared for by Dr Mayer, an experienced ophthalmologist, and in a good hospital, consisted in cloudiness of the left cornea The limbus was covered by a gelatinous swelling, the upper and lower portions of the cornea were infiltrated with dry, yellow masses, and in the center, fibroid degeneration in the form of a leucoma had occurred The entire conjunctiva was much swollen and reddened, traversed by dilated vessels, three large arteries approached the cornea, near the middle vessel upon the sclerotic was a yellow, round, flat nodule 3 to 4 mm in diameter, immovable and covered by the movable conjunctiva, a smaller arterial branch terminated at its edge Beyond the hunchback there was nothing indicative of scrofulosis, elsewhere, especially no enlarged glands She weighed only fifty eight and three fourth pounds and despite the good diet of the hospital, she was thirty pounds short of her normal weight, according to Quetelete's tables

Specific treatment was applied from October 15 to November 22, beginning with 5 milligrams, and increasing to 1 cubic centimeter, in all 13 7 cubic centimeters Its effect upon the eye was early observable The gelatinous swelling disappeared first under contraction of the vessels, then the yellow infiltration upon the upper segment of the cornea began to clear, became smaller and was gone on the twenty-fourth day The lower yellow spot also had by this time become much smaller, the dilatation of the vessels had disappeared There was no more lacrymation or pain On the thirty first day the episcleral spot had also entirely disappeared

Her general condition, in the meanwhile, gave place to a striking change for the better, menstruation had occurred, her appearance was much better, she had gained four pounds in weight

A slight relapse occurred upon the eye the following month, but was quickly controlled by a few more injections The central fibroid degeneration was so far improved that the patient could count fingers at 5 meters, which she could not do before, at half the distance The patient was then discharged but suffered subsequently from two more tuberculous deposits On March 20, she returned with a diffuse swelling on the lower border of the left lower maxilla, which was incised, but discharged only a small quantity of thin pus, after eighteen injections some of which were finally made into the swelling, the latter disappeared entirely A similar swelling occurred at the head of the left fibula disappearing after three local injections Finally, on May following a bush-like dilation of a conjunctival vessel near the lower border, with a small gelatinous infiltration of the edge of the cornea developed, which disappeared after one injection which was made into the subconjunctival tissue Since that time the girl has remained well

I have related this case more in detail, because it is rarely that we can observe upon the human subject in so satisfactory a manner, that which I had repeatedly observed to be the action of tuberculin and of antiphthisin in the animal experiment, namely, the entire disappearance of tubercular tissue or deposits without reaction

---

[2] Klebs Tuberculose page 332.

[3] Klebs Tuberculose page 328

In this case it could not be shown, as I have done in the animal experiment, that the conversion and re-absorption of tubercular tissue is preceded by the degeneration and disappearance of the tubercle bacilli, but there is no good reason to doubt that in both instances the same course obtains, and that, under the use of the remedy the tubercle bacilli are directly injured and their virulence destroyed entirely so, as one can demonstrate it to occur in the test tube

The following experiments made by me and published in my work on "Tuberculosis,"[4] may be of interest in this connection Of five guinea pigs born on the same day, two were infected on July 1, 1892, with tubercle bacilli which had been kept five days in a solution of the remedy, while the other three were infected with bacilli from the same culture, but without exposing them to the effect of the remedy, on the eighth day, the three last animals showed a marked difference in their growth, having only gained 11, 50, and 59 grams respectively, whereas those which were infected with bacilli treated with the remedy, had gained 105, and 110 grams The three sick animals were killed, two on July 30 and one on August 24, and were far advanced in tuberculosis, whereas, in one of the other two, killed August 4, no tubercular lesion was found The second animal was killed a year later It had reached its full growth, weighing 681 grams, and showed only the local changes in the abdominal cavity which Prudden and Hodenpyl have shown to be characteristic after the injection of dead tubercle bacilli

Case 5—H B, age 9 years, (the sister of Case 4) was referred to me by Dr Ruppert, of the Vicentius Hospital The pale, poorly nourished child had been treated for some time without result for an affection of the knee joint Could walk only with crutches, *the left knee presented a spindle-form swelling (tumor albus) involving the* external soft parts, while the interior of the joint was filled with soft fungoid masses

The injections were made in part, peri- and in part intra-articular, altogether in the first month 6 72 cubic centimeters were used in twenty-two injections No increase occurred in the inflammatory processes, on the contrary after the fourth injection, the pain was materially diminished, during the second half of the *month the child could walk* without crutches, *and on the twenty-fourth day the swelling had entirely disappeared, nothing* of the fungoid masses could be longer detected and after the faulty position of the limb had been corrected by the application of an isinglass bandage, the child was discharged Three months later the child presented herself to me, *having the appearance of perfect health* Inasmuch, however, as no other evidence of tuberculosis was present, it might be urged that the affection may not have been of a tubercular character, but I believe that the history *of the sister's case, and the result of the treatment would refute such an objection*

The third class of cases are those in which both, the

INVOLVEMENT OF THE LYMPHATIC GLANDS AND OF THE BONES,

bear unmistakable evidence of scrofulosis, cases which, however, differ from the others only quantitatively, as to the extent of the disease These are cases which at the present time are exclusively referred to the surgeon, inasmuch as every other method of treatment is unavailing But even for the surgeon, such patients are not the most desirable, because of the extensive tubercular processes and the obstinate relapses which are observed

I am of opinion that when in such cases multiple deposits exist in the osseous structures, even the operative treatment becomes of doubtful utility because beside the observable and removable deposits, smaller and not observable ones are frequently present, which, although still latent at operation, are apt to develop rapidly thereafter, and in any operative interference the danger of dissemination is ever present

The following three cases were treated in the Diakonissen Hospital and referred by its surgeon, Dr Baer In only one case was the result entirely satisfactory, of the other two, one indeed improved, but a permanent result was not obtained, for reasons which will become apparent

Case 6—S D, aged 3½ years, a well nourished girl Resection had been made of right elbow joint, on account of fungoid caries The child presented numerous scrofulous ulcers communicating partly with the bone, partly with lymphatic glands, many of them fistulous, especially upon the right arm and neck Patient received forty injections between November 1 and Dec 17, 1892, in all 7 cubic centimeters *A small abscess was incised on the right wrist joint, and was treated locally with the remedy* Discharged December 17, when all wounds, ulcers and fistulæ were entirely closed, and all glandular swellings had disappeared. A year thereafter the child had remained free from relapse and was entirely well

Case 7—Isabella T, 5½ years of age, fairly well nourished, but pale, suffered from an enormous number of scrofulous ulcers upon the face, neck and extremities which communicated *mostly with glands, but also with bony parts* The right metatarsal bones upon which several operative procedures had failed, presented a cheesy mass, while the leg of the same side presented long cicatrices, but also ulcerations and swellings in connection with the bones and glands Under the specific injections most of the ulcerations healed, but new swellings occurred constantly, and the condition of the metatarsal bones in spite of again repeated partial resection could not be brought to a cure *In the course of the treatment the child had the measles, which certainly was* not favorable to her recovery In spite of large doses increased to 1 gram per day, and of long continued treatment, the result was only partial Since, with a slight exception, no septic complications were present at any time, the failure can not be attributed to sepsis, but must be looked for in the extensive distribution of tuberculosis and in the deficient blood *conditions I therefore* advised the employment of salt water baths, and *climatic influences* for her general improvement I have not been able to learn the further result Another hindrance in the treatment was the great number of subcutaneous injections, altogether 130 in number, which became very painful Unfortunately, I had at that time not yet learned that the rectal injection of the remedy is equally efficacious, which method of administration I now recommend, especially *in practice* with children

The last, Case 8, of the scrofulous diseases in childhood which came under my care was a boy aged 10, with suppurating tubercular coxitis In this case a short course of injections was without any benefit, and the failure emphasizes the fact that under complicating suppuration and sepsis, the latter must be removed before resorting to specific treatment

While the material which I submit to you is not very large, I nevertheless believe it sufficient to show that particularly in the tubercular affections of childhood, antiphthisin offers most favorable prospects, the selection of cases is of the greatest importance, and we can only then expect its fullest benefit when we select cases which present neither septic complications nor conditions of exhaustion and marasmus, and you will doubtless also appreciate that there are cases, which on account of the great extent of the purely tubercular disease may fail to make a recovery

These limitations, however, suggest that we should employ the remedy in the early periods of the disease, and that we should not lose valuable time in the employment of symptomatic treatment only

Finally, I wish to point out that, in all tubercular affections, the same as in many other severe and serious diseases, their treatment in hospitals or special institutions offers great advantages over that of private practice

---

[4] Klebs' Tuberculosis

In Europe numerous institutions for the treatment of children have been established, and should the profession in this country desire it, the Winyah Sanitarium, at Asheville, N C, will be glad to establish a special institution for tubercular children upon the most approved and advanced principles, and with every essential for their care

The excellent climatic conditions of its location would permit their treatment in the open air at all times of the year

DISCUSSION

Dr Larrabee—No one is warranted in making a diagnosis of tubercular meningitis who has not sat at least an hour at the bedside of the child No practitioner who has sat at the bedside of a child an hour will fail to make a proper diagnosis of tubercular meningitis If the three symptoms are there together, it is tubercular meningitis, therefore the importance of emphasizing all these symptoms In the first place there must be some evident deterioration, some disturbance of the mental and physical condition There must be at the same time the knitting of the eyebrow, or the convulsed lid There must be the contracted abdomen, and there must be constipation These three symptoms, and the valuable symptom of projectile vomiting, make a case of tubercular meningitis The projectile vomiting is valuable in showing the disturbance from the center to the periphery But that alone must not diagnose the case There must be the peculiar knitting of the eyebrows, and the constipated bowel and the dilated bowel If the four run together, you are absolutely certain, although the three symptoms are sufficient for the diagnosis ordinarily Whoever takes the history of the family and relies on the statement of the friends in this examination, will often find himself mistaken Large hospital experience from day to day teaches the truth of the words of the lamented great surgeon, who was crowned both in Europe and America with laurels When closing his life he said "Two thirds of the civilized world have syphilis, either hereditary or acquired"

Whenever I give iodid of potash to a child and cure his bronchitis, I consider it a very fortunate result I might say I have touched in the dark the diathesis I say also that when I give these cases of brain trouble iodid of potash, and they get well, I put it down in my category that I have struck a trail, and that I have stumbled upon a recovery in a case where I could not by any questioning or examination find a specific cause The well-known fatality of these cases, the necessarily fatal results of tubercular meningitis, forbid that we should record cases of recovery, and the Doctor is evidently very correct in that

As to the difficulty in the diagnosis of pneumonia, I suppose it is unnecessary to repeat all the difficulties of that diagnosis There is only one way to get out of it, and that is in every case to make an examination of the chest Make it a routine every time

We have before us to day one of the most distinguished gentlemen in either Europe or America, Professor Klebs (Applause) It is a great misfortune that the investigations and researches of Professor Koch were published when they were It was premature, and he objected to it, and he was made to say that which he never thought of saying I was in Berlin at the time and was conversant with the ideas then prevailing, but the London papers got hold of the thing and published it as a cure of consumption which nobody had thought of That publication produced a feeling that has thrown discredit upon all efforts in the direction of Professor Koch's researches

The study of tuberculosis in childhood is an especially interesting one, for the reason that it is only in childhood that we have so many diverse manifestations and the only reason of that is because we have so many growing centers Tuberculosis, like everything else of a morbid character attacks that part at which the greatest activity is manifested In the adult we expect to find tuberculosis in the lung, while in a child we may not find it in the lung but find it everywhere Where there is the greatest activity and growth, that part invites the tubercular bacillus My friend Dr Von Ruck, has admitted the term tuberculosis, but I am sorry he has tied a string to it It is said that scrofulosis is associated with or is part of the tuberculosis in infant childhood We do not believe in the transmission of the tubercular bacillus If a babe be born with tubercular bacillus, it is not going to live long enough to trouble anybody I recognize in scrofula a disease depending upon a debility, born of debility and born of hygienic surroundings, and attended by increase in fibrous tissue We have in the scrofulous subject a tendency to the increase of fatty tissue, the thickening of the lips and nose When the child arrives at the age of 20 or 21, we never hear of scrofula, unless it is engrafted upon the system

Dr Lyon of Connecticut—I would like to ask Professor Klebs, through Dr Von Ruck, what distinction he makes in his use of tuberculin and antitoxin—what difference he makes in the use of the two? In the second place, if he would use them both as diagnostic or both as curative, and whether he so instructs the medical profession I ask these questions to call out answers from him

Dr Upson—I ask Professor Klebs whether antiphthisin is effective when given by the mouth?

Dr Parsons—In my paper I did not mean to depreciate in any sense the importance which attaches itself to this tubercular bacillus My point was illustrated better than I could do it by the remarks of Professor Larrabee, regarding scrofulosis

Dr Griffith—I want to say one thing in support of the idea that this may have been a case of tubercular meningitis which recovered I think we find it more manifest daily that there is a vast amount of dogmatism in medicine I think it possible that perhaps tubercular meningitis may recover There was a case reported not long ago of a child who did recover, and it was proved before recovery that it was tubercular meningitis, by obtaining fluid from the spinal column in which the bacilli were discovered, and yet the child recovered What is proved to have happened *once*, may happen many times, and we are not in a position to say that every case is tubercular meningitis that dies, and every case that gets well is not tubercular meningitis We can not state that

In regard to the diagnosis of pneumonia, I think Dr Larrabee misunderstood me, if he understood me to say that we must not examine the lungs very carefully I say not only that, but that in spite of the examination of the lungs we fail many time in making a true diagnosis The pain in the abdomen is not a symptom in itself of anything important, but when combined with other things is a very important matter

Professor Klebs spoke in German —At the conclusion of his remarks, several gentlemen in the Section requested the Chairman to ask Dr Von Ruck if he would translate into English the substance of Professor Klebs' statements, that those not understanding German might have the benefit of his discourse

Dr Von Ruck made the following statement there is practically no difference between tuberculosis and scrofulosis Scrofulosis represents a tubercular infection in a state of latency at times, but becomes more manifest when glandular, and other manifestations, such as retarded growth and development show themselves The clinician only sees the manifestation in the form of nutritive disturbance, and the tubercular tissue is hidden from his observation This nutritive disturbance, as for instance the thickened upper lip and nose, and the otherwise arrested development of the child, are produced by intoxications with substances representing the products of the tubercular bacilli at the point of their localization If any proof is necessary that these scrofulosis manifestations are of a tubercular character, it is apparent from the distinctly tubercular manifestations which result when the cheesy glands break down and when their products are absorbed into the circulation, either through the lymphatics, or when the tubercular process has perforated a vein, in which case miliary tuberculosis or localization of new tubercular eruptions in distant organs become manifest

If scrofulosis were not primarily tuberculosis, how could we explain the appearance of such distinctly tubercular manifestations following immediately upon the softening and breaking down of the specific scrofulosis new formations? These scrofulous deposits must contain the tubercular bacillus, for it is only through their absorption that the more acutely tubercular infection becomes manifest, and it could not be conceived that in these non-bacillar deposits the tubercular bacillus should have found entrance after their generation, unless we would again return to the theory of spontaneous generation These are all facts that have been demonstrated anatomically and pathologically over and over again, and stronger proof than has been adduced in that direction, it would be impossible to furnish But whatever the practitioner wishes to maintain, I can only recommend to you that he subject those cases of latent or more manifest scrofulosis affections to the test of specific medication, which I can assure you is perfectly safe and harmless, and under which, if the process is a truly tubercular one, these manifestations will quickly disappear, furnishing such results of still further evidence of the truly tubercular character of scrofulosis

As to the diagnostic value of tuberculin, the same has never failed us in the experiments with the lower animals, and will be found equally satisfactory in its application to the human being I must, however, warn against the employment of tuberculin as a diagnosticant in cases where extensive tuberculosis is already present, and in which from the clinical history and course of the disease there should be no reasonable doubt as to the nature of the malady On the contrary, I would advise the use of such a test only when a disease is entirely latent and only manifest by the nutritive disturbance heretofore mentioned, in which case the test is made rather for exclusion of the tuberculosis than for the confirmation of its presence If any of the gentlemen who desire to do so, use tuberculin in the adult, I would advise the hypodermic injection of 5 milligrams, say about 9 o'clock in the morning, after having previously made a complete record of temperature preceding the test for one or two days If, now, a distinct rise of temperature occurs, say within about twenty-four hours, then the evidence is conclusive that the tubercular process is present in the individual The test failing, the experiment should be repeated in the course of three or four days This time, however, with a larger dose of 10 milligrams, with the same observation of temperature before and after its application No temperature reaction occurring to those doses, we can safely conclude that in the individual experimented upon, no active tubercular tissue is present

In children, the first dose for trial could be much less, and the temperature reaction would probably take place from the administration of from 5 to 1 milligram A second dose can be made with 2 5 or 3 milligrams, and a final one with 5 milligrams, with the same precautions as spoken of for the adult

For some time past, however, I have not applied tuberculin for diagnostic purposes in the human subject, but have used the toxalbumins precipitate in the manufacture of antiphthisin A definite amount of the organic substance being present, we can apply this substance with much greater precision, inasmuch as tuberculin varies considerably in the amount of organic substance contained in different specimens

The process of manufacture of antitoxin is as follows we take the ripe culture of the tubercular bacillus and reduce it to one-tenth of the original amount by evaporation in a vacuum This really is the tuberculin as prepared by Professor Koch With this substance we now apply an acid solution of soda iodid of bismuth, and obtain a precipitate which is filtered out This precipitate represents the toxic properties of tuberculin as proved by me both in the animal experiment and in its application to the human being for diagnostic purposes It produces the characteristic general reactions manifest in chill, malaise, aching, depression with rise of temperature and subsequent defervescence, just as we see in the beginning of all infectious diseases It also exerts slight curative properties in the lower animals, but larger doses prove fatal, and entirely so, as does tuberculin Taking now the filtrate After the toxic albumins are filtered out, we can precipitate further by the addition of absolute alcohol and an organic substance resembling in its chemic reaction a peptone, and this organic substance redissolved in distilled water, so that the organic substance present is antitoxin

In the animal experiment we find that this alcoholic precipitate does not produce fever or toxic symptoms of any kind This is so in the human subject as well, but the animal infected with tuberculosis can be cured therewith just the same as we can do with tuberculin, and that in the human subject the tubercular tissue is re-absorbed without the production of any concomitant symptoms of an undesirable character

Dr Larrabee—How about tubercular meningitis after a supposed diagnosis of the case?

Dr Von Ruck—I have not treated any cases myself of tubercular meningitis

SCORBUTUS IN INFANCY

Read in the Section on Diseases of Children, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10 1805

BY I N LOVE, M D

VICE PRESIDENT, AMERICAN MEDICAL ASSOCIATION, 1894

ST LOUIS, MO

Prior to 1891, when the report of eleven cases of scorbutus in infancy was made by Dr Northrup to the American Pediatric Society, I had never observed a case, at least I had never recognized it Going back over an experience of sixteen years, the first five of which were spent in the eleemosynary institutions of St Louis, including one year's service at the General Dispensary under the control of the Health Department, which was the receiving station for the distribution of all patients to the various hospitals of the city and where a very large number of outdoor patients were constantly treated, ranging from one hundred to one hundred and fifty cases a day (the medical colleges of St Louis not having at that time established their private clinics), a number of cases come to mind with their various symptoms suggesting scorbutus, but such cases were invariably found in family practice rather than in public institutions There can be no question as to the importance of the disease

Since the appearance of Northrup's paper in 1891, five cases have come under observation, and they uniformly occurred in the families of the well-to do One case had been fed for ten months with sterilized milk too largely diluted with barley-water, and investigation elicited the fact that equal parts of sterilized milk and a strong solution of barley-water had been the food given

Another case, one of a pair of twins, eight months old, who had been fed with boiled cow's milk largely diluted with plain water and lime-water Both were almost typical specimens of marasmus There had been a very evident failure of assimilation from the beginning, and marked gastro-intestinal irritation. The parents and the attendants had been deceived by the fact that the children being very small at birth and delicate were disposed to sleep almost constantly, and this, they thought, gave evidence of their being satisfied and getting a sufficient amount of food Insufficient food and the consequent hunger usually results in a considerable amount of fretting and crying My being summoned was dependent upon the fact that a few days before, one of the children who had been so uniformly amiable and sleepy, had suddenly developed marked disposition to fret and gave evidence of the presence of pain when handled. I observed, upon examination, a swelling around the right femur in its lower third, with great tenderness, the child crying lustily when the part was handled. Examination of the mouth revealed the fact that the gums were spongy and bled readily No teeth had as yet appeared The swelling of the thigh increased and by the second day purpuric spots appeared at various points upon the surface of the child. It died of exhaustion within three days from the time of my first visit An interesting feature in this case was, that of two children surrounded by exactly the same conditions, one should develop scurvy and the other should not, both, of course, preceded by a history of marasmus The surviving child was given liberally of beef juice, orange juice, and fresh cow's milk, given, when possible, directly from the cow It was surprising to see how rapidly the child began to thrive, and it soon became well nourished

A case came under observation, nine months old, which had been treated from birth, it had been poorly nourished and it was found to have a few spots of pemphigus blebs about the nates shortly after birth A diagnosis of congenital syphilis was made and the child treated accordingly The mother was delicate and very evidently her milk had been poor in quality and quantity The child did not thrive and though further local expressions of syphilis did not appear, it was supposed to be a case of syphilitic marasmus Acute symptoms of great distress and swelling of both thighs developed, on being called into the case, after careful examination, finding puffy bleeding gums and pronounced extravasation of blood in tissues about both femurs, I made a diagnosis of scorbutus This child had been nursed by its mother, who had been kept constantly under mercury almost to the point of salivation The child had also been given mercurials most of the time during its life, and this together with evident insufficiency of food as regards quantity and quality, evidenced that the condition of the child was due to mercury more than syphilis, indeed, I was of opinion that it did not have syphilis at all I stopped all mercurials and administered raw beef juice to the child and occasionally a teaspoonful of orange juice with water Analysis having demonstrated that the mother's milk was in every way deficient and the general condition of the mother being very unfavorable, I at once ordered the child to be weaned and carefully substituted good fresh cow's milk, diluted with a small quantity of water, and added thereto a teaspoonful of Mellin's Food

By careful, systematic feeding, watching the secretions, the child began to improve within a few days and ere many months had passed was finely developed

It is well to emphasize the thought that this disease is most frequently mistaken for rheumatism, stomatitis, rickets, sarcoma arthritis and infantile paralysis As in the majority of diseases which confront us, the important thing is the making of the diagnosis promptly and the removal of the cause, the latter being uniformly dietetic We can not too thoroughly emphasize the thought that scurvy in infants, as well as in adults, is uniformly produced by the lack of certain nutritive elements, certain organic acids, such as citric, tartaric acid, and in combination with potash These special elements are known to be contained abundantly in fresh vegetables and fruit juices, in raw meat and raw milk, and the evidence is certainly accumulating from many directions and my own experience corroborates it, that the modern craze for the sterilization, the complete desiccation of milk tends toward scurvy Of course, it goes without saying, that unsanitary conditions, the lack of sunshine and fresh air increase the tendency to this disease

The reading of the existing literature upon the subject and the careful weighing of the evidence furnished by my own experience and observation, justify the following conclusions

1 That we must impress upon the mothers of the children under our care that, in artificial feeding, something additional is needed beside a food that will stay with the child or apparently agree with it, in other words, that an absence of marked evidence of indigestion does not necessarily mean assimilation

2 More stress on the part of the family physician should be laid upon the tissue building powers of the food presented The primitive mothers who permitted their children early to have some of the food from the table in small quantities were not far wrong, for there can be no doubt that the general nutrition of the child was more completely subserved

In artificial feeding we have a divided duty, regard for the stomach and a general disturbed alimentary canal will often necessitate the temporary use of a food which should not long be continued Many of the commercial foods often meet a temporary emergency and are valuable to that extent Certain it is that the modifying material which can be combined with fresh cow's milk in such a manner as to facilitate digestion by the breaking up of the curd, which is the disturbing element in cow's milk, and at the same time furnish additional elements of nutrition and not interfere with or destroy the elements presented in the milk, which are anti-scorbutic, is a desideratum, and such we have in Mellin's Food

My experience agrees with that of Dr Davis at the Philadelphia Hospital reported in the *American Journal of Medical Sciences*, June, 1891, to the effect that, although sterilized milk often cured and prevented gastro enteric disturbance, the nourishment of the child is insufficient and unless guarded they will pass into a condition of marasmus For the meeting of emergencies, the correction of a gastro-intestinal disturbance, for temporary use in such cases, they are very valuable

Certainly the evidence is overwhelming that children brought up on dried foods without any modification of conditions, soon become pale, flabby and deficient in vitality and even present symptoms of rickets There can be no doubt that the fresh secretion from the mammary glands of the cow, ass or goat, the same as with the human mother, furnish the fresh animal element necessary to proper nutrition

The earliest records of infantile scorbutus appeared in Germany from 1859 to 1873, made by Moller, Bohn, Hirschsprung, Senator and Ingilve, the first appearing in England being made by Mr T Smith in 1876, but not recognized as scorbutic Borrough and Cheadle, of England, were the first liberal contributors to the subject Up to a recent date there was no record of infantile scurvy having been met with in America Since the first able presentment of the subject by Northrup in 1891 there have been a number of contributions upon the subject, notably those of Crandall, Fruitnight, Winters, Booker, Jacobi, Holt, Carr, Louis Starr, Rotch, Henry Ling Taylor, and more recently Egan, Blackader, and Hollopeter, so that the evidence is accumulating that infantile scurvy is a definite entity and general practitioners should be on the alert for it Indeed, we may safely say that the literature regarding this subject is one of the most important and valuable contributions to the fund of general medicine made by pediatric workers

DISCUSSION

Dr Atkinson, of Baltimore—I am very far from denying the occurrence of scurvy in infants It is, however, a condition that must be extremely rare Upon the subject of artificial food for children, there are many conditions lacking in artificially prepared food Nobody doubts that The lack of proper nutrition is more accountable for ill effects than the insufficiency of the properties in the food Condensed milk, properly condensed, is just as perfect food as cow's milk not condensed Not so good as mother's milk, but condensed milk with 75 per cent of its water drawn off by evaporation is just as good as simple cow's milk It keeps longer Condensed milk is simply preserved milk Condensed milk is as much of a preserve as a can of preserved strawberries Each pound of condensed milk contains a quarter of a pound of cane sugar But this is a question, however, that has led me away from the one at issue, which is scurvy in infants We have hemorrhagica occurring in active children as in adults, it might be mistaken for scurvy, and if it lasts long enough will run into conditions that make it hard to distinguish from scurvy—conditions that assimulate scurvy very closely I do not think the cause of which the Doctor speaks was the saving condition, but I think it was the correction of the error in the nourishment of the child that brought about the improvement As I said before I do not state that there is no such thing as scurvy in children, but do say that if there is scurvy as a condition in nursing children, it is a thing of rare occurrence That it may occur, I do not deny, but in nearly every case where there are conditions that assimulate scurvy, it is simply assimulating scurvy and nothing more It is marasmus, or purpura hemorrhagica and allied conditions that bring the vitality of the child to a low ebb

Dr Bishop, of Maryland—There is a percentage of children who die who can undoubtedly have their lives spared by the proper treatment of the mother The proper condition of the mother will result in a live child, and a child whose health may be prolonged for a greater or less length of time It seems to me that one question hinges on the other in these various papers The question of heredity is one of the things involved A child who has a hereditary fault in its physical condition requires different care from that of a perfectly healthy child I think there is a mistake made by some of you gentlemen who have the care of infants in large cities I listened with a great deal of interest to the care of children as described by Dr Cotton But I think instead of their taking such care of these weak children, it would be a much more humane thing to let them die There are quite a large number of children who go to hospitals, as well as in private practice, who ought to be allowed to die It is not a humane thing to let a child that is a victim of the disease of its parent, live as a child and die as an adult Such a child ought to be eliminated from society, because of the evil effect it produces in after life People who have such constitutions are more apt to reproduce in a hurry than those who have perfect physical systems Persons who are predisposed to consumption are much more likely to marry, and, being married, much more likely to have children, than persons of perfect physical formation and conditions I have noticed it as well in the vegetable kingdom The diseased peach tree will produce twice the fruit—certain classes of diseased trees—that a healthy tree will produce It seems to me there ought to be a certain amount of care taken not to permit these diseased children to grow up Let their parents nurse them There is another thing that we are in fault in, so far as regards feeding the child on artificial food Instead of taking good care of the cow that it may produce good artificial food for the child, it would be better to take good care of the mother that she may produce good natural food for the child These artificially prepared foods are good as a rule, but occasionally children are killed by them

Dr Love—The prenatal feeding of the child is an important thing Indeed, I think the physician should keep in mind the wellbeing of the child prior to its conception even The proper and healthful condition of the mother, and all that concerns the child should be considered That opens up a broad field The question of matrimony, the question of who should marry and who should not, enter into it No one knows better than a doctor that the main questions in the matter of matrimony are recklessly disregarded I see my friend Dr Hutchinson, of Des Moines, Iowa He has been a very able writer on this subject of whether marriage is a failure, and all that goes with that particular problem, and I should be glad if the subject could be opened up along those lines

The statement of the last speaker, suggesting that there are some children that ought to be permitted to die, is certainly one that we can not entertain at all Where is there a mother on earth who would consent that her particular infant should be permitted to die? Where is the father, worthy of the name of father, who would consent that his child should be permitted to die? and another thing the physician has no right to entertain, is the matter of life and death The desire to save, has developed new means of salvation Not a baby that can be conceived is so insignificant as not to be worthy of our most profound consideration We may have there the germ of a Garfield or Lincoln or Marion Sims, or Shakespeare, and so on The proposition laid down by our friend can not be entertained at all

The point thrown out by Dr Atkinson, suggesting that he feels that most of these cases come under the head of bad nutrition, etc, is important, but when there is presented to us a baby with such profound symptoms, a baby who has been poorly nourished, and there should suddenly appear great distress, a suggestion of rheumatism of the leg, and marked evidence of extravasation of blood, and there is no question about the pathologic condition, and examination reveals the gums bleeding, almost suggestive of a fungous condition, you then have the same conditions exactly that you find in scurvy in the adult There can be no doubt of scurvy in infants The evidence presented in our meetings by its workers is worthy of profound consideration These workers come from a country whose practice covers a thousand hills, and their testimony is valuable Then we have the testimony of Dr Cotton, our Chairman, who is located in a large city, having to do with all kinds and conditions of children He sees more sick children, I have no doubt, one hundred to one, with special conditions, than he saw twenty years ago when he practiced up in the interior of Illinois, although he was a busy country practitioner The evidence of Dr Cotton along these lines is important In reading the evidence presented to us by Dr Booker and others, we should weigh it thoroughly When a man located in a large city gives his observations, and in addition those as a specialist, in observing the children in the world to-day, and places before us his views as an expert, such evidence is very important The words and views of Dr Atkinson on this subject of scurvy in infants are important

The earliest records of infantile scurvy appeared in Germany from 1859 to 1873, made by Muller and others The first records that appeared in the English language were by Dr Smith in 1876, but then it was not recognized as scurvy Burrow and Schiedel of England, were the first contributors to the subject Since the presentation by Northrup in 1891, there have been a number of contributions on the subject, and I have enumerated the same in my paper I do not mean to say that scurvy in infants is frequently found My cases of scurvy have been found in the houses of the well-to-do, and not among the poor I believe the general practitioner should be on the alert for scurvy in infants, and I think the literature on the subject is most valuable

Dr Valentine, of New York—The remarks of my friend Dr Love, suggest a point that I have wished for an opportunity to bring before this meeting He says that a healthy mother is required to bring forth a healthy child This is manifestly a self evident proposition Is it not a fact that it is within the experience of every one of us, although not engaged in the special work to which this Section is devoted, that a healthy vigorous young girl will marry a man in apparently exceedingly good health, and that shortly thereafter she will complain of pains, rather vague in character, and the girl shows all manner of symptoms which give her friends cause for congratulation The error is soon manifest The girl sinks Perhaps a tumor is found in the abdomen The tumor grows on that one side, and the other symptoms of abdominal irritation suggest the presence of a foreign body in the pelvis, which entails the necessity of an operation to save this woman's life A microscopic examination of the majority of tumors, be they of the ovaries or the tubes, shows the presence of gonococci I am not engaged in children's diseases, but mainly with the fathers of these children, and principally before they are married I have frequently had occasion to observe manifestations of latent gonorrhea, so called by courtesy It is because of defective examination that we do not discover the gonococci Why not? Because of the difficulties entailed by the examination Those who favored me by listening to my paper on modern urethroscopy will agree with me that it is criminal for a man to marry who has had gonorrhea, unless it be proved that he is free from the power of infection Only by destroying the ostii where the gonococci are assembled, where they are latent, can we extirpate the germ It is only by destroying these that we can utterly destroy this disease A week after destroying them it is my habit to make an injection with nitrate of silver I think I can then with a clear conscience consent to that man's marriage

Why should this be in the hands of a specialist? Are not the lives of women and children of sufficient importance to the general practitioner? I hold that the time has come when we should have the temerity to put ourselves on record as advocating the enactment of a law requiring, as a condition necessary to marriage, the certificate of a physician that this man who proposes to get married can not infect his wife with gonorrhea

Dr Hutchinson, of Iowa—I think Dr Valentine's remarks ought to be emphasized by this Section The number of deaths caused by the gonococci is something to which the profession is just waking up I happened to have a most painful case of some trouble of this nature brought to my notice a short time ago We ought to insist upon sounding a danger signal with reference to this infection that is impairing the fruitfulness of the finest women in our country We should advocate some sentiment on the subject It would be a difficult law to enforce, and I do not think we can get at the evil through legislation I should regret the taking of any action that would prohibit marriage on the part of any portion of humanity, because I believe that it might result in something worse I think, however, it would be well to call the attention of the public to the danger to which women and children are exposed by this disease

THE ETIOLOGY OF INFANTILE DIARRHEA

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association Baltimore Md, May 7 10 1895

BY ROSA ENGELMAN, M D

CHICAGO

In order to arrive at any just conception of the subject, attention must be directed to the entire alimentary canal, as well as to milk, the staple food of infancy and childhood A straight almost indifferentiated tube swarms from mouth to arms, with facultative, obligate, saprophytic and pathogenic germs Milk, particularly during the heated term, is fertile soil for various fermentations microbic contamination, and the exogenous as well as endogenous development of toxins An unclean mouth, a slight error in diet, constitutional taint, immature sensitive cellular metabolism invite these germs to unusual lodgment and activity

Their great number and variety exclude a specific relation to the particular disease manifestations under consideration The question resolves itself into a discussion of the toxemic, septicemic or pyemic genesis of the several morbid gastro-intestinal disturbances, in which not one or a few, but many and various microörganisms play a part

Escherich long since proved that there is a great simplicity and uniformity of bacterial vegetation, and that increase and variety was due to changes in diet

He demonstrated the constant harmless presence of the bacterium lactis aerogenes and bacterium coli commune in the upper and lower bowel, respectively, and their relationship to normal digestion The assumption of pathogenic attributes by these germs was likewise disclosed

The rise and evolution of the biologic field revealed the shortcomings of a purely pathologico anatomic classification of infantile diarrhea This disorder was in turn ascribed to 1, disordered structure and function inherent to an undeveloped organism, 2, atmospheric and telluric influences, 3, the chemic constituents, metamorphoses and amount of food ingested, 4, the omnipresent germ The far-sighted Hueppe foresaw the dangers of biased opinions He says "For a time, under the influence of Darwinism, bacteriology ran into absolute generalizations, and differentiating signs were not sufficiently valued Then the opposite mistake was made, in that differences were overrated and a one-sided conception of microbial species, specific effects and special products was adduced Toxemia of intestinal origin is foreshadowed by him in his statement that the specific microorganism is not alone the cause of the disease The significance and evolutionary phase of the above cited factors were for a time swamped in the omnipotent germ theory The effort to discover specific microorganisms as the causative agents of the different degrees and forms of diarrhea proved futile, but led to the revelations of Escherich, Baginsky, Stadlhagen, Hueppe, Huebner, Booker, Jeffries, Abelons, Sevestre, Vaughan, Czerny, Moser, and many others They established the non specificity of the various gastro intestinal diseases, and gave to us a wide knowledge of the untold microbic hordes, regular, accidental or pathogenic occupants of the alimentary tract

These scientists likewise confirmed the interdependence of bio chemic operations and the relations of these germs to the several diarrheal disorders and give to us a reasonable basis for the following postulate indigestion, slight to severe gastro intestinal catarrh, and even a foudroyant attack of cholera infantum may be primarily ascribed to an intoxication; this intoxication being caused by an absorption (little or much, slow or rapid) of toxic, tissue and bacterial products, elaborated without or within the body. Intestinal lesions ensuing, the microbic horde, led by such germs as the bacterium coli commune, bacterium lactis aerogenes, staphylococcus pyogenes, streptococcus pyogenes, pneumococcus and others, invade the blood and give rise to general systemic or localized infection, a fulminate or insidious septicemia. Thus also can we secondarily account for pneumonia, meningitis, encephalitis, nephritis, etc, of intestinal genesis

An accumulation in the food, and concentration in the gut of saprophytes and their toxins explain the inception of a gastro enteritis, the continuance of which maintains the irritation of an exceedingly susceptible mucous membrane and its nervous director, the coliac plexus

The unstable abdominal brain that presides over an enormous circulatory territory succumbs to the saprogenic poison Consequently neither specific nor pathogenic intermediary need be concerned in an attack of cholera infantum From the fact, however, that the latter includes a number of morbid entities, it might at another time be the result of an overwhelming septicemia instead of toxemia On the other hand, chronic enterocolitis and pedatrophy might arise from sluggishly acting germs associated with slow, prolonged, poisonous absorption It has recently been shown that acute enterocolitis results from the invasion of the blood by numerous germs that have been hitherto considered specific only to certain other processes

A Rodet and G Roux in 1892, differentiated between the infectious and poisonous properties of the bacterium coli commune It and the bacterium lactis aerogenes had been acknowledged harmless intestinal tenants The former's pathogenic and pyogenic attributes were now recognized as well as its areas of invasion, viz, serous surfaces, skin, glands, respiratory and urinary organs It is thus the admitted disease inciter of such sundry conditions as enterocolitis, pneumonia, meningitis, encephalitis, phlegmon, peritonitis, etc Its clinical, pathologic and biologic resemblance to the typhoid bacillus is being carefully considered

Fraenkel tells us that, "pathogenesis is the most inconstant thing in the character of many species of bacteria" Fraenkel's pneumococcus, often a most virulent inflammatory exciter, is likewise a regular tenant of health salivary and nasal secretions as are the pus germs and Loffler's bacillus

A P Ohlmacher in the *New York Medical Journal* April 27, reports finding the diphtheria bacillus in a pneumonic lung in which the diplococcus of pneumonia was absent The diplococcus was obtained, however, in cultures made from the pus in the meninges of the same patient Future research will probably throw light upon the curious analogies and associations of these microorganisms and their more definite relations to such diverse disease manifestations Much work in this direction has, however, been accomplished in the study of infantile diarrhea The non-specificity of this affection has been proved, as has also its general toxemic and septicemic origin

Sévestré as early as 1887 said "A general infection, especially a condition of pulmonary congestion and broncho-pneumonia, may develop, secondary to fetid diarrhea and infectious enteritis" Under his supervision, Gaston and Renard, by capillary puncture of pneumonic lungs during the life of children suffering from enterocolitis, secured therefrom and from the stools of the same patients, pure cultures of the staphylococcus, pneumococcus and bacterium coli commune and other microbes Their control experiments upon animals demonstrated that these germs entered the general circulation through the intestinal lymphatics and lodged in the first filter, the lungs

Rossi Doria publishes an epidemic of diarrhea due to the bacterium coli commune, that remaining *in loco* caused acute enterocolitis, that entering the circulation caused a systemic typhoid-like infection as proven by the pathologico-anatomic findings

Czerny and Moser recognizing the general infectious character of infantile diarrhea, and traced its source through the lymphatics into the general circulation They discovered the staphylococcus pyogenes, streptococcus pyogenes, bacterium coli commune, bacterium lactis aerogenes, and other well-known disease progenitors in the stools and circulating blood, of twelve out of fifteen babes suffering from uncomplicated enterocolitis Their work was carefully controlled by experiments upon dyspeptics, healthy children and animals Their pathologic findings in the lungs and kidneys corroborated their bacteriologic and microscopic work All these careful observations but emphasize the dictum as to a general nonspecific systemic infection in acute gastro enteritis The slighter and earlier intestinal disturbances are of toxemic origin and due to milk fermentation and contamination Chronic enterocolitis is the result of a slower, more insidious poison or sepsis Cholera infantum is either or both an overwhelming toxemia or septicemia Associated conditions, or the so-called secondary complications are of clearly septicemic or pyemic character, in which not one but several different germs play an important rôle Dyspepsia, acute and chronic enterocolitis, cholera infantum, may be but different and various degrees of toxemia and septicemia dependent upon numberless and manifold saprophytic, pathogenic microorganisms

COLITIS IN INFANCY AND CHILDHOOD

Read in the Section on Diseases of Children, at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md, May 7-10 1895

BY EDWARD ANDERSON, M D

ROCKVILLE MD

Colitis, in the adult, often occurs as a primary disease, but this is rarely the case in infancy At an early age it usually begins as an enteritis and is most always caused by indigestible substances irritating and obstructing the small intestine Bottle-fed infants are particularly prone to this disease and I believe that most of those who die, waste away from its effects

Intussusception is spoken of, as of frequent occurrence in connection with it I have never seen it, though obstruction more or less complete, I believe, is always present Heat is an important factor in its causation, as is proved by its being confined almost exclusively to the hot months of the year A heated atmosphere not only renders the infant's bowels incapable of digestion, but also its food unfit for use, even when we can not perceive it by the taste An enteritis sometimes runs into a colitis, but the former is generally converted into the latter by treatment with opiates and astringents A child that is deriving its sustenance from a healthy mother, when attacked by inflammatory diarrhea from being overheated or from any other cause, can generally be relieved at once by the administration of tincture of opium, bismuth and chalk mixture, but not so the bottle-fed infant It usually goes on from bad to worse under this same treatment, as does also the child beyond the nursing period

I will not detain you with a lengthy discourse on the origin, symptoms and progress of this disease, with which you are familiar, but will cite three cases which I hope will prove of interest

July 3, last, I was called to see a little three months old female child, in a family I had always attended The parents had three other children, all of whom had been nurtured at the mother's breast, and when attacked by diarrhea were almost immediately restored to heath by the administration of opium, bismuth and chalk mixture, but not so this youngest, who was being raised artificially The parents had become familiar with my prescription, as persons too often do, and had treated their older children successfully with it, but this youngest child they had treated into a case of ulcerative colitis with the same remedies I prefer mechanical means in the treatment of disease, wherever they can be employed, so I attempted to use the syringe in this case but failed It required some force to introduce the nozzle of the syringe and the water was thrown back as rapidly as injected Had I persisted, the only question would have been which was the stronger, the bowel or the syringe Having failed with everything else, I took a pill containing 2 grains of blue mass and half a grain of opium, that I always carry for adult cases, and divided it into twenty pills, ordering one such pill to be given every four hours I continued this treatment for two weeks by which time improvement was so great that the amount was reduced to three pills a day and enemas could be satisfactorily employed When first called to see the child it was being fed on condensed milk which was changed for a more laxative diet, cow's milk with dextrine At the end of a month this child was perfectly well and is now one of the most robust children I know

From former experience I feel convinced that had this little patient been treated in any other way it would have wasted and died

On Aug 10, 1894, I was called to see a male child five months old, suffering from ulcerative colitis This child had been treated by another physician for two months and was gradually getting worse all the time A sister at the same age had died a year before affected in the same way I was put in charge of the case and treated it in the same way as I did the last, except that instead of directing the blue mass and opium pill to be divided into twenty parts, I divided them into ten, giving a fifth of a grain of blue mass and a twentieth of opium every four hours After two weeks, fecal matter began to descend freely, when I ordered a syringe to be used after every action that was not perfectly satisfactory At the end of a month this child was well and has remained so since

About June 20, 1894, a little 5 year old son of a Rockville druggist was attacked by inflammation of the bowels, the nature of which I could not clearly determine as he was attended by another physician of this place who had been their family physician before I settled in Rockville He treated the case until July 18, when I was called in consultation I not only met the attending physician but a prominent physician from Washington also Another physician of at least thirty years' experience had been in consultation but I did not meet him until later on I found the child a mere shell, lying on his back and unable to move He could not have turned on his side if a red-hot iron had been thrust in his face When I entered the front door the house had the odor of a dissecting room, although the sick boy was upstairs The mother said he had had but one action that day, which I requested them to let me see, and found it nothing but necrosed tissue The father, who is one of the most intelligent and best informed men I ever knew, said not a particle of fecal matter had been passed for ten days The attending physician never expressed an opinion in regard to the case, at least in my presence, but the consultants were of opinion that intussusception was present and rather favored the treatment then being employed that by opium, bismuth and tannic acid, although the child was dying under its use They did not speak decidedly as to what should be done with the little patient, but were opposed to my plan of treatment, which was to give a grain of blue mass and one fourth of a grain opium every four hours until the child improved sufficiently to have the number of doses reduced, and then employ enemas The consultant whom I met July 18 said he would be afraid to try an enema at that time, for fear the bowel would burst, as he believed that in many places there was nothing left of the colon but its peritoneal coat I saw no more of this case until July 23, when I received a note from the child's father, asking me to take entire charge of the case, as he believed I was the only one who could save his boy He notified the attending physician to that effect

I had been giving my patient a grain of blue mass with one fourth of a grain of opium every four hours for three days when the second consultant came up He considered my treatment heroic, but said as the child would die anyhow, I was justified in trying it, but he would advise me not to keep it up for more than three days I continued it for two weeks with improvement from the very first I then stopped it for three days, when I was obliged to resume it on account of retrogression I kept it up until September 18, when the boy was able to walk and eat solid food This patient was fed with milk and dextrine mixed together and with extract of malt, and I allowed him to chew as much beef, mutton and chicken as he wanted and swallow the juice There was so much weakness present that two teaspoonfuls of whisky and a drop of fluid extract of digitalis had to be given every four hours, also one-sixtieth of a grain of strychnia three times daily to prevent sinking

When I first saw the child he could take no nourishment, even a tablespoonful of milk had to be forced down his throat Blue mass, on account of its sweet taste, is very easily administered to children, and can be dissolved in a few drops of water In using this treatment in cases such as I have described, we should not restrict ourselves to a day, week or month, but give it until the patient is well, for it never produces constitutional effects in dysentery except in tuberculous individuals, and with them it should never be employed It used to be thought and is now generally supposed that no one is as sound after a severe attack of dysentery as he was before, but I have never treated a case by the prolonged use of mercury where the health was not improved thereby except in tuberculous subjects Why the mercury produces no constitutional effect I am unable to say, for it certainly enters the circulation, or it would not act on the kidneys as it does In no other disease can it be given with such impunity To sum up all I have to say, in regard to the treatment of this disease from which so many infants, and especially bottle fed infants, slowly pass away and from which few, if any, should die the child should be put on a nourishing liquid diet, which should be laxative in character, the colon should be irrigated with warm water from a fountain syringe as soon as the inflammation of that viscus has sufficiently subsided to retain it, blue mass and opium should be administered in doses suitable to the age of the patient, until all irritating and obstructing substances are removed from the intestines and their natural function is restored In this way, mercury, the best of antiseptics, will be kept continually pouring over the diseased coat or coats of the bowel during the process of repair

---

Diuretic Action of Calomel —Dr Finkelstein at Charkoff, Russia, summarizes his experience as follows 1, calomel is an excellent diuretic and especially useful in cardiac dropsy, 2 the prognosis is less favorable in aortic disease, 3, the action is greater in the absence of renal complications (except suggestion), 4, the dosage must be guarded (maximum 12 gm every two hours), the first symptoms of mercurial poisoning must be closely heeded, 5, in case of a weak heart, a combination of calomel and digitalis is recommended (℞ calomel 12-13 gm., pulv fol digitalis 02-30 gm S Dose, four times a day), 6, the effects of calomel are continued longer than in the case of other similar remedies —*Therapeutische Wochenschrift*, July 25, 1895

PSEUDO-MEMBRANOUS ENTERITIS ASSOCIATED WITH ASCARES LUMBRICOIDES

Read in the Section on Diseases of Children, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7-10, 1895

BY IRVING M SNOW, M D

INSTRUCTOR IN DISEASES OF CHILDREN, UNIVERSITY OF BUFFALO, PHYSICIAN TO BUFFALO FRESH AIR MISSION HOSPITAL ETC

BUFFALO, N Y

(SYNOPSIS)

This case of pseudo-membranous enteritis occurred in a girl of 2½ years During the summer of 1894 she suffered from a severe attack of whooping cough, followed by ileo-colitis lasting six weeks In the most acute stage of the diarrhea she began to pass pieces of membrane and tubular casts of the bowels, six weeks later, the membranes being daily present in the feces, several round worms were evacuated, after which no more membrane appeared in the stools for four and one-half months, when, coincident with an attack of grippe-bronchitis, bits of membrane and two ascarides were passed for two days No recurrence of the membrane casts since

On Sept 27, 1894, a little German girl aged 2½ years was brought to me with the following history father dead of sarcoma of the rectum, mother and one sister living The patient was born after a normal labor and reared on condensed milk During dentition she frequently suffered from bronchitis, five or six attacks in all In June 1894, she was quite ill from vaccination After the vaccine fever she was attacked by pertussis and was harassed by a frequent paroxysmal cough in July and August In August the whooping cough was further complicated by an inflammatory diarrhea The acute stage of the ileo-colitis lasted three weeks there being ten or eleven stools of blood and mucus daily The mother watched the discharges with anxiety, having recently nursed her husband, who died of malignant disease of the bowels On August 25, the diarrhea being at its height, she observed, mixed with the passage, bits of membrane and a long ribbon-like whitish substance This she separated from the blood and feces by pouring water over it The mass filled one-half of a 6 oz vial, it was twelve inches long, the surface was honeycombed with small apertures Its shape was like a narrow piece of cloth It formed a tube in which a finger could be introduced and around which it fitted like a glove

From this time the diarrhea gradually subsided and the child slowly gained in health, yet from August 25 to September 27, thirty-four days, each day the feces were mixed with tubular casts and bits of membrane Some days there were membranous tubes, at other times only pieces of membrane Blood was occasionally present in the evacuations until September 20 The passage of the stools and membrane was accompanied by no pain or colic either before, during, or after defecation

Such was the history of the case up to the time of my examination

September 27 my patient was a strong, ruddy, well-grown little girl of placid temperament The tongue was clean, appetite good, sleep natural The child was on adult diet There was no abnormal tenderness, nor was anything abnormal found in chest, abdomen or urinary organs The stools numbered two a day, were of the consistency and color of mustard and contained no undigested food The membranous cast passed that morning was shown to me It was tubular in form, fitted closely about my little finger, whitish in color, thin, glistening, transparent in texture, three inches long, one third inch in diameter It had kept its shape in alcohol for two hours, and did not tear easily I made no chemic or microscopic examination, expecting to have another specimen to examine, which was not the case

I prescribed cod-liver oil, an out-of-door life, generous diet, and directed the patient to be brought to me in a few days On October 1 the mother related to me that the quantity of membrane passed was much smaller, being only seen the first two days after my prescription On October 9, the mother reported that the day before the girl had passed a piece of membrane, and that just before she came to my office she had passed a round worm, the first the child had ever had One or two passages a day, patient's weight twenty-seven pounds

As all descriptions of membranous enteritis state that shreds of membrane may be mistaken for worms, I advised the mother to continue the cod-liver oil, and to closely examine each stool The girl continued in good health, albeit somewhat feverish on October 17 A week later, to decide as to the presence of worms, I administered calomel and santonin As a result of this medication two ascarides ten and six and three-fourths inches long were evacuated, but no membrane Two days later, after more santonin and calomel, two more round worms, eleven and six inches, were discharged No membrane The medication proved quite severe, for after it the child was weak, exhausted and feverish

From the last of October until February 15 the child was in superb health, but in the middle of February she was attacked with grippe and bronchitis, being ill three weeks On March 3 a laxative produced loose stools which for two days contained bits of membrane, but no mucous cylinders March 6 to 7, two large lumbricoid worms were passed after doses of calomel and santonin The repetition of the anthelmintic brought away no more

From the last date, until now, the child has continued in good condition, neither mucous cylinders nor ascarides have been observed in the feces

It is to be noted that the discharge of casts and membrane practically ceased in October, the depression of health in February caused the exudation of only minute pieces of membrane You will note that no elaborate chemic or microscopic examination is presented There was no opportunity to do so as the membrane in the feces stopped abruptly, possibly from the tonic effect of the cod-liver oil. Nevertheless the composition of such tubular casts of the intestine is well known They are generally formed by mucin exuded from the muciparous glands of the intestine, the glands of Lieberkuhn Although many learned authorities deny the fact, it is certain that the casts may contain fibrin as well as mucin Their place of origin is generally the colon, rarely the small intestine

The interesting features of the case are

1 Membranous enteritis is rare in children, nearly all cases being recorded as occurring in women of hysterical neurotic temperament Of 111 cases recorded up to 1894, only 6 were reported in children under 10 years

2 The clinical history of the case is unusual In the descriptions of membranous enteritis, the passage of the tubular exudation casts is said to be painful, being preceded by malaise, abdominal colic and tenderness, accompanied by pain and tenesmus and followed by constitutional disturbance In my case the condition was the sequel of an acute ulcerative ileo-colitis, the exudation casts appeared in the stools, mixed with blood and mucus, at the height of the acute infectious process They were continually present during the subsidence and after the termination of the malady Thus they were daily evacuated while the child was rapidly gaining strength Four months later during a grippe-bronchitis a few bits of membrane were passed Nor did their discharge cause the child any more discomfort than the passage of a normal stool Neither colic, tenesmus, nor abdominal tenderness could be traced to their presence.

3 The relationship of the ascarides to the casts is obscure Undoubtedly the parasite found lodging in the child during the depression of health from the colitis It is possible that the mechanical irritation of the worm may have caused the exudation of mucus Yet the habitat of the ascares lumbricoides is in the small intestine, while the exudation casts judging from their caliber originated in the colon, nevertheless round intestinal worms are commonly seen in young children, while membranous enteritis is excessively rare in early life As round worms were undoubtedly present in the intestines two or three months after the tubular casts had disappeared, it is the opinion of the author that the association was accidental Whether the condition is a phase of mucous disease the author will leave for discussion.

Loos describes a similar case in an article in the *Prag Med Wochenschrift*, 1889

" A 2 year old boy, previously in perfect health, was taken suddenly ill He cried the whole night with abdominal pain, and finally voided a single stool, which contained a peculiar substance An examination showed it to be a tube 18 centimeters long and 4 centimeters wide It was composed of fibers, some running parallel with the length, others branching in various directions These fibers were connected by a glistening homogenous membrane The whole was enveloped by cloudy membrane The tissue was concentrically built and held in its substance pigment, eggs of oxyuris, intestinal epithelium and *debris* of food, chemically, mucin and fibrin were present The membrane continued to be present in the stools ten days, the general condition remaining good Fourteen days later, there was discharge of a large number of ascarides Rudolph von Jaksch finds the process to be a periodical exudation of mucus which causes the colic The condition is analogous to chronic bronchial catarrh "

SULPHATE OF MAGNESIUM IN THE SUMMER DIARRHEA OF CHILDREN

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY STUART PATTERSON, M D

PITTSBURG, PA

The use of magnesium sulphate in the treatment of cholera æstiva is not new, particularly in the rural districts

It is unnecessary to go into detail as to the history, symptomatology, etc , therefore I shall merely review the conditions present and the indications for treatment As yet, no specific cause has been found, but we can almost certainly conclude that there " are fermentative and septic processes in the contents of the stomach and intestines, and these followed by production of large quantities of lactic and fatty acids "[1]

According to Escherich, Baginsky, Booker, Vaughan, Lesage and others, these changes are most probably brought about by microorganisms gaining entrance into the alimentary canal with the food

The following are the reasons for the belief in the specific origin of the disease

1 It is one occurring for the most part in epidemic form during the summer months, a time when fermentative processes are most common Or, if it does occur in winter, it is almost invariably found in close, ill-ventilated, and crowded quarters (Epstein)

2 The majority of those attacked are the offspring of the poorer classes, who have both insufficient and unwholesome food, and this brings about an ill-nourished and consequently a weakened condition of the organism, which furnishes a proper nidus for the growth and development of fermentative fungi

In many of the cases of this report, the mothers were women who could only nurse their children morning and evening, while for the rest of the day the little ones were left to the tender mercies of careless and ignorant brothers and sisters

3 In the great majority of these cases, except those seen during the first twelve to twenty-four hours of the disease, the discharges from the bowels were acid It has been found that fermentative fungi are present in vast numbers in all the stools, but are *especially* numerous in those having an acid reaction (Nothnagel)

Henoch, vol II, p 42, in the absence of a recognized specfic cause, explains the primary process as " an abnormal chemic action in the contents of the stomach and intestines, set up by unknown influences, and not merely a catarrhal process, although on microscopic examination, proliferation of round cells has been found under the mucous membrane " This can be and is produced, if the process goes on for several days, by the irritating contents of the intestines

The cause, whatever it may be, finds its way into the stomach and intestines, in all likelihood, through the ingested food and water The indications for the treatment are to remove the cause if known, and prophylaxis To meet the first, magnesium sulphate seems to me to be, theoretically at least, the ideal remedy As to its practical utility, this report will speak for itself To meet the second indication, sterilize the food

The administration of sulphate of magnesium calls forth a profuse secretion from the intestinal glands The remedy is a powerful alkali It stimulates peristalsis, either directly or indirectly, through the quantity of secretion poured out or by producing a free flow of bile—one of the natural stimulants to peristalsis

Thus we have a remedy which, 1, corrects the irritating properties of the contents of the stomach and intestines by rendering them alkalin , 2, stimulates the glands to a more profuse secretion, thereby unloading a congested mucous membrane and possibly washing out the products of fermentation , 3, flushing the entire bowel, thereby removing the fermenting mass

In the first series of twenty-five selected cases treated during August, 1892, at the Pittsburg Free Dispensary, which I report, the symptoms were those usually found in the disease under discussion, namely, vomiting, diarrhea—ranging from the " chopped spinach " stools, mixed with mucus and streaked with blood, to the rice water discharges—coated tongue, restlessness and general prostration, etc

The ages ranged from 1 to 6 years The dose and mode of administration of the remedy were as follows the mother was directed to give to a child 1 year old an even teaspoonful (about 1 drachm) of sulphate of magnesium, sufficiently moistened to swallow, as soon as she arrived home , the process to be repeated in the morning and the child brought back to me at 3 o'clock P M on that day, that being the hour of my service at the dispensary

This procedure was repeated daily at the same hours until the discharges become yellow For the older children, the dose ranged from a heaping teaspoonful (about 2 drachms) to a tablespoonful (about 4 drachms)

As the result of the exhibition of these doses, the mothers reported the children relieved of pain and restlessness, with the induction of quiet sleep No difficulty, except in a few cases, was experienced in the administration of the remedy on account of its objectionable taste The after-treatment consisted of general tonics

Report of the duration of the disease, first series one case, nineteen days , one case, five days , two cases, four days , seventeen cases, three days , four cases, two days

In the second series of fifty-five cases, treated during 1893 and 1894, the results were slightly different Ages 6 months to 9 years two cases died , four cases, fourteen days , six cases, seven days , twenty-three cases, five days , thirteen cases, three days , seven did not report after the first day

In the cases lasting over one week, the children suffered relapses and several were sent to the Children's Hospital The other cases all did well, and I saw them thriving under a properly regulated diet and tonics I should add that in the latter series I gave guaiacol for several days after the stools became normal The tonics were selected according to the necessities of each case Those most frequently used were syrup of iodid of iron, cod-liver oil, compound syrup hypophosphites, strychnin, quinin, pyrophosphate of iron, etc

---

[1] Henoch, vol i page 128

This list includes all the cases that were selected for trial by this remedy, and the practically uniformly beneficial results obtained in the treatment of this so often intractable disease have led me to give you the benefit of my experience

DISCUSSION ON PAPERS OF DRS ENGELMAN, ANDERSON, SNOW AND PATTERSON

DR KOPLIK—Taking up the paper of Dr Engelman, of Chicago, I might say that most of us have met those cases in which there is the presence of toxemic and septicemic symptoms The prognoses given in those cases are generally faulty, but lately I have seen some of them cured, even though the pneumonia lasts a fortnight This is due directly, as we suppose, to microbic influences from the gut

Now as to the treatment of some of these cases of diarrhea in children One of the gentlemen here to-day spoke of calomel, and the other spoke of magnesium sulphate Both of the ideas are the same, but I think in acute intestinal catarrh, and especially in that form called cholera infantum, we should be careful in the use of mercury in any form In acute gastro enteritis in infancy, and in young childhood, we have to deal with the sensitiveness of the kidneys, for instance We have to contend with cases where it is likely the use of mercury in any form will cause death As to magnesium sulphate, it answers the same purpose, and it is better than castor oil, or any like remedies which we are accustomed to use in the beginning of the treatment of those diseases It is scientific and proper to try to clean out of the bowels that which is injurious, as well as that which is toxemic and septicemic We should first recollect that most of these cases are due to some error in the diet, either bad food or good food improperly prepared So that the first thing in all these cases after you have begun the medicinal treatment is to stop all diet, diet which requires any amount of effort on the part of the intestines, such as milk In my practice, that is the first thing to think of It has been said in rebuttal, whenever I have mentioned this fact, that the child would starve You would be surprised how long a child can live upon a simple mixture of the white of an egg and water I think the only safety of the child lies in starving it at the outset, and in the beginning of the treatment we should direct our attention to the diet and stop it, and afterward gradually return to it

The medicinal treatment in acute gastro-enteritis has been very unsatisfactory I use little medicine in the treatment of acute and chronic gastro enteritis, and I can assure the Section that I see about as many such cases as are seen in any hospital I use very few drugs, probably a little resorcin, and probably a good deal of bismuth I might say that I consider bismuth a sort of standby It is a mild intestinal tonic

DR W D BOOKER, of Baltimore—In considering the etiology of infantile summer diarrhea, it is important to think of something beside bacteria as the cause We have the bacteria operative in the winter time, and the same bacteria may be found in the intestines of infants in winter as well as summer There must be a predisposing cause operating therefore by which the microorganisms are brought forth What that secondary cause may be, we are not so well informed It is possible that the direct effect is the prostrating of the digestive powers of the infant, and probably the weakening of the cells of the intestines themselves There must be then, beside the bacteria entering into the etiology of summer diarrhea, many conditions that we do not understand Now, the question is, in what way must we consider first the action of the bacteria before they enter the body, second, the action of the bacteria after they have entered the body In summer time the bacteria multiply much more rapidly than in the cold of winter, and they cause much more serious effects in summer than in winter Milk especially, which is the food of the child, is very favorable to the growth and activity of bacteria But a short time in summer is sufficient to permit very serious changes in the milk, and poisonous qualities to be introduced by the microörganisms, unless something happens to the intestines before the bacteria get in As soon as these cells are injured in any way the bacteria have an opportunity of getting in their work Beside the heat itself, we have to contend with the improper food I do not mean the food that is made improper by the bacteria, but rather the imprudent feeding of the child with food that is entirely unsuited for its digestion, such as green potatoes, strawberries and the early vegetables In nearly every case we are called upon to treat, we first inquire as to the origin of the disease and get the answer that there has been some imprudence in the matter of diet If we keep off this meddling in the diet the resistance of the cells is preserved, or their entirety preserved, and their resisting qualities are sufficient to beat off the bacteria After this lesion is once established, it is easy for the bacteria to do their work, and this they do as has been outlined in the paper read here in two ways, one by the production of poisonous properties in the intestines, which are absorbed and taken up in the various parts of the body, and the lesions made by these poisons are similar to what we get in diseases like diphtheria Again, this poison, which is produced by the bacteria in the intestines, may also act directly on the tissues, and we get lesions which show the various stages of the bacteria in their direct effect As the bacteria spread we have produced superficial ulceration The bacteria become more and more numerous and the process extends to a deeper ulceration, which may pass down as far as the external muscular coat There is no difficulty, in some cases, in tracing bacteria along this line, first through the superficial layer that has been broken, and so on Where we trace this bacteria, we find the separative processes going on

Now, what are the forms of the bacteria that we find in summer diarrhea? Investigations which I have made for the past few years on this subject have led me to the belief that we find the same bacteria that we find every day There is nothing specific in the nature of these organisms, and the nature of the disease is so variable that there is no classification found in one text-book that will correspond with that found in another In classifying the cases from the contents of the rectum, I have made classifications in about eighty cases, according to the various forms of the bacteria, and not with regard to the clinical condition of the patient It is interesting to see how this classification runs The first classification consists of the cases which show decided toxism. They have not developed any serious inflammatory changes in the intestines to be traced by any condition in the stools, but the child shows drowsiness and much nervousness. These cases are generally more or less serious

The next class is twenty or thirty cases in which the streptococci prevail Nearly all these cases show inflammatory changes in the cells in the mucus and feces These cases are generally more serious because of complications by other lesions Not only the complication from the absorption of the toxin particles, but also the invasion of these organs by the bacteria themselves This secondary infection is more apt to follow in cases in which the streptococci is found There are few cases in which the micrococci alone is seen

In regard to the treatment of summer diarrhea, I think the most important consideration is dietary and not medicinal There are very few medicines that we can rely upon, and I was very sorry to hear Dr Koplik speak against one that I have always thought wise to use The first thing to do, as Dr Koplik said, is to stop everything at the time the sickness occurs If it be milk or any other food that was being taken, at the time the child became sick, stop it at once I think this is better done by substituting rice water or oatmeal water for the milk, and to give some purgative I have for years used calomel, and have not seen any bad results from it Of all the drugs in the Pharmacopœia, in cases like this, calomel is the one I use It acts not only by relieving the stomach of its contents, but there is an action of the calomel upon the mucous membranes generally that we do not understand It is my belief that this is a valuable remedy

THE CHAIRMAN—What dose of calomel do you give?

DR BOOKER—It should be given in very small doses To a child six months old, a sixth of a grain should be given every hour until a grain or more is taken Calomel acts somewhat as an antiseptic If we get rid of the fermentation, and give the child food that it will digest with the least amount of effort, and which produces the least amount of poisonous product from the bacteria, the disease can be checked very early I think in the majority of cases of summer diarrhea, if taken in the beginning and treated as to diet and if we administer purgatives in the beginning, and gradually go back to the milk, and not be in too big a hurry about it, we can carry a child on cereal water for several days without serious results If restlessness on the part of the parent should occur on account of taking the milk from the child and substituting cereal waters, then egg water is very good The white of the egg should be beaten up and allowed to stand for a few hours in a cold place Then pour the clear part off from the bottom, and a teaspoonful of this clear white of the egg can be dissolved in three or four teaspoonfuls of clear water, and be given as a substitute for the cereal waters After the disease has gone on for a week or couple of weeks, medicine does not have much effect, and diet must be the main reliance

The most important point in all the treatment is not to give too much food Do not be afraid of starvation, but give the smallest quantity that the child can digest Later on, the opiates may be necessary In certain cases nothing will relieve the restlessness and pain and frequency of stools like the opiates, but care should be used in giving them The smallest quantity should be given and no rashness exercised in this respect Bismuth is more or less disappointing We all give it because we are puzzled in these difficult cases to know what to do, but in a few cases, perhaps bismuth does give marked relief In cases that become discouraging, it is hard to find anything that is good Irrigation sometimes gives relief, but we should select the cases in which irrigation is resorted to Where there is an inflamed condition of the intestines, it is a question whether irrigation should be carried on, but if irrigation is carried on under those conditions, it is well to raise the buttocks of the child, holding the shoulders and letting the water run in by gravitation

In those cases where there is drowsiness and stupor and frequent stools with more or less fever, irrigation will often relieve all the symptoms in a few hours, but to do this irrigation thoroughly the catheter should be inserted as far as it will go—its full length—and from one to two gallons of water can be used The water is running in and out, all the time There is no danger of rupture of the gut, and a free irrigation in these cases, as a rule, relieves the symptoms I have seen the fever disappear after such an irrigation of the child, and it becomes bright and lively where previously it had been stupid

DR. RIGG, of Pennsylvania—It is my belief that there are other influences than bacteria The clearing out of the bowel and stopping of food are certainly two of the first things to be sought After that the course is not so clear I want to speak more especially of one particular type of diarrhea I believe we do not discriminate closely enough between the different types In that form of gastro-colitis where we have watery stools and vomiting, with great prostration, I know of nothing equal to nitrate of silver In my own hands, that has been the most satisfactory drug I have ever used After the food is stopped and the alimentary canal cleared out, then give a water solution, small doses of nitrate of silver often repeated I do not know why this acts as it does, other than it is astringent I think it is sometimes in that case like other cases of irritation of the mucous membrane, we get in a short time the effect of an irritation It may take quite a while to get rid of the effects If you get an irritating substance in the eye, it will produce an inflammation that will make you treat the condition at once, and not pay any attention to the cause So it is in these other cases The nitrate of silver, I do not believe has anything to do with the removal of the cause, but it has to do with the healing of the bowels and the stopping of the watery diarrhea

DR GRIFFITH, of Philadelphia—I think the heat in our cities is a great factor, not by increasing the germs inside or outside of the body, but in the general condition of the child. I can not account in any other way for the benefit that invariably follows the sending of a child into the country as soon as possible It is our custom in Philadelphia to send the mother with the child for a trip on the river, where we have a steamboat for the purpose The babes who go on these trips apparently dying, come back in a very much improved condition No change has been made in the diet, and nothing has been done except to remove the child from the excessive heat of the city So we have every reason to believe that the heat has as much to do with many of these cases as anything else

With regard to treatment, I, too, want to add my voice to those who favor starvation I think the starvation of the child, after all, is the most important thing you can do Most mothers in the dispensary class, and it is in that class we see most of these cases, are not willing to see the children starve, and on that account I advise them to give barley water, and where nourishment is required I prefer the egg water We have to remember always what we are dealing with, what the child is suffering from at the time, and what the stage of the malady probably is The large intestines of children dying from diarrhea are found to contain comparatively few germs The germs have been washed out of the small intestines, and therefore it is not right to give the child a purgative with a view of washing out the small intestines when the diarrhea has gone on long enough to wash them out As to the purgatives, whether castor oil, or magnesium, or what not, depends somewhat on the stage of the case If we think that the small bowel is comparatively empty, and the large bowel is not, that calls for certain treatment What drug we shall use, depends on the condition of the case If we feel that a large number of bacteria is present, and are doing the damage, then we might use an antiseptic, but I have little faith in intestinal antisepsis I want to add my voice to those already heard here in favor of the use of opium in these cases A few years ago the man who would advocate opium would have been called a know-nothing I think now that many believe opium must be the standby in the future If we are sure, from giving no food, that the bacteria will have no longer anything to live on, and that we have emptied the intestinal canal, we see very clearly that we have to do with something that is acting from the inside, and our remedies then must be directed to the treatment on the inside, and in those cases where a child is suffering evidently from frequent and profuse passages, opium will do work that no other drug will do

I do not want it to be understood that I advocate a routine treatment with opium A few years ago I made experiments in the Children's Hospital with different drugs in the treatment of summer diarrhea, putting some children on starvation, and some on bismuth, and nothing else, and giving some opium and nothing else I found that those that had the starvation treatment did as well as any of those that had no drug but opium

DR WEAVER—It seems to me that in private practice it is impossible to give magnesium on account of the disagreeable taste I do not see how in ordinary practice it is possible to administer magnesium I know it is impossible for me to use this medicine with any degree of utility We have remedies that are more palatable, and except where you want to experiment for the sake of seeing the effect of the medicine, it seems to me it is unnecessary to use a remedy like magnesium

I approve entirely of the treatment which has been so well outlined by the gentleman from Baltimore, and the gentleman from Philadelphia, and in the end I think it will prove better than anything else I agree with them that the best method is the elimination of every offensive particle from the bowel, and the taking away of food I am in the habit, in those severe cases, of putting the child on a diet of hot water slightly sweetened I find that the child likes it very well After feeding a child last summer on hot water sweetened, I found when I wanted to return to the milk, that the child refused to take it It had learned to like the sweetened water I am very sure that the hot water had a great deal to do with the effectiveness of the treatment Calomel I have great faith in, and I think we are on the right path when we use it to clear the alimentary canal I think opiates necessary I use morphia with 1-150 of atropia

DR FISCHER—Dr Neumann, after making an extensive study of this subject in Germany last summer, said that the routine method of treating was first to sterilize the intestinal tract and then sterilize the food Beside washing the stomach, the bowel was irrigated by raising the child and allowing the warm water to flow by gravity as high up as possible At any rate his plan was to wash the stomach and rectum with a saline solution, and he said that if the child's pulse was very weak and the diarrhea severe, in addition to washing they use this hypodermic clysis in whatever quantity necessary to flow under the skin I have used this hypodermic clysis several times, but only in these true forms of cholera infantum as we see them in New York, and have found them beneficial

I should like to come back to what Dr Griffith has said in regard to taking children away from the heat of the city, putting them on boats and sending them on the water I should like to emphasize that more strongly than Dr Griffith has We all know that salt water is binding Passengers on the ocean complain of the constipating influences of the sea trip, and therefore the child not only has the benefit of the fresh air, on one of these boat-trips, but also has the benefit of the constipating influence of the salt air

There is one drug that I have seen used abroad with good success After the intestinal tract has been sterilized, and after the administration of the castor oil or magnesium, and whatever it may be, the drug that is giving the most satisfactory effect abroad is beta-naphthole bismuth It is an ordinary bismuth combined with naphthole It is not poisonous, is very well taken by the child, and I have found that it produced good results in those cases where I have used it

Dr S S Adams, of Washington—My experience has taught me that a great deal can be done simply by removing the child from the heat of the city This was impressed upon me more forcibly last summer than ever before From June 8, until the middle of September, we had in Washington almost continuously a temperature above 80, with its usual ill effects upon infantile life During this period I was attending the little ones in the Foundling Hospital We removed the children from the commodious quarters of the city to a suburban place in what is called the National Park Although this tract has been bought by the Government, it has not been improved yet, and a large house, occupying quite an elevation, with a stream of water running through the place was the new home for the little ones, It was a most favorable locality and the best that could be selected for the purpose Unfortunately, however, the children were so closely packed together in this farm house, that there was hardly 300 cubic feet for each child I had ample opportunity for making examinations, and was surprised at certain things which these examinations developed Fifty per cent of the children removed to this place died, and of that number the largest number of stools passed by any in twenty-four hours, was ten This was a very small number in cases ending with such fatal consequences The average number of stools in the children who died was six There were no intestinal lesions in those who died The conclusion that must be arrived at in such cases is that these ill effects were due to heat In spite of the elevation of the place, the temperature, night and day, ranged from 85 to 90, when there was a free circulation of air It is just possible that at some time during this period there was contamination from a sewer that emptied above The city water, however, was in use there all the time I believe a great number of deaths were due to the excessive heat I visited the institution in the morning and got the history of each child's night The next day I would probably be told that that the child had during the night a couple of stools, and they would be exhibited to me They would show some caseine, and there were evidences of some intestinal disturbance It was not unusual for the messenger to come to my office later in the day, and inform me that the child was dead Of course these things were not easily reconciled to my mind I had heard from gentlemen who are connected with institutions having from 900 to 1,000 foundlings and young children, that such cases were not rare, but personally I had no such experience These cases were treated upon the principles laid down by Drs Booker and Griffith I must agree with those gentlemen that a great mistake is made in not drawing the line between irrigation and injection Some inject instead of irrigate If you do not provide for the return current, you will not get the beneficial effects that you expect In this connection, I will relate an incident On June 22, last, I saw a child with gastrocolitis It was an aggravated case, and had convulsions I think he was 27 months old He lay in a state of coma for several days, and finally, I came to the conclusion that he would die if not taken away The child was kept alive from Thursday to the following Monday with brandy and water Nothing else passed his lips The treatment of the rectum was tried without success He was kept alive in this condition until July 12 On that day I went to the signal office, and ascertained that another hot wave was coming, and would reach its greatest intensity on the Sunday following I at once informed the mother that there was no chance for the child to recover in the city, and that it must go away The child had had during this period from twelve to twenty bloody stools a day At 12 o'clock at night, in company with the nurse and mother, we started with the child for New York We reached the Hudson pier the next morning and took the steamer north on our way to the Catskill Mountains The mother got it into her mind that this was the only place to go That night the child had had twelve stools He was in a very low condition At this time he was being fed on chicken jelly and lamb broth Going from the elevator the temperature in the car was 110 The child was fanned and I thought he would die every minute I have heard those who said that they could count a pulse beating at 160 or 180 I can not do that When I felt this child's pulse, I could not, however, notice anything more than a flutter The child had not spoken for two weeks By the time we had reached the top of the grade and had got the benefit of the changed temperature, the child asked me if I would take him out riding When we got to the hotel he had one stool in the morning and another at 11 o'clock at night, and did not have another for forty eight hours He had no medicine whatever during all that time but whisky, and I attribute the recovery solely to the change of climate I believe that if the child had remained in Washington, he would not have survived, as the temperature the following Sunday reached 105 in the shade The child returned home in a healthy condition

I was once called up to the mountains of Maryland around Frederick, and found a child in about the same condition as the one I have referred to It had had twelve stools during the day At 10 30 at night on the top of the mountain the thermometer registered 86 outside on the porch I expressed the opinion that the child could not survive in such a temperature He was taken to Narragansett Pier, and to my surprise he never had any more bloody stools after he reached there, and he became well without any medication whatever Such cases illustrate the beneficial influence of change of climate

Dr Anderson, I think, is very fortunate in his expression I do not think that we can place much reliance upon dispensary statistics I do not believe that in the majority of dispensary cases, the traatment is carried out, as far as the diet is concerned The appeal of the child has great weight with the family, and even in our institution, I have caught people smuggling things to the children in the hospital For instance, in the case of typhoid fever, where they are warned to the contrary, we have had nurses take a can of cabbage and bacon from under the skirt and give it to a patient I agree with Dr Weaver that it is difficult to get anybody to take sulphate of magnesium I tried it once myself, but I do not want to try it again

Dr Anderson—There is no question about heat being almost exclusively the cause of these cases In the country we can not take our children to the Adirondacks, or to the Catskill Mountains, or to the springs, but we can take them from the upper story to the cellar, and often save them that way I lost a valuable member of a family I knew well, by administering a dose of chenipodium My rule is to give either calomel or blue mass Blue mass can be dissolved in a little water Mercury in certain of these severe cases is the only thing you can give You can not use irrigation in the beginning There is a spasmodic contraction of the bowels often, and in the case I mentioned the bowel had sloughed

Dr Snow—In a certain number of cases that I had charge of in a hospital, it was the reduction of temperature that seemed to be most difficult The vomiting would break after a day or two, and the number of discharges were diminished from seven or eight a day to two or three, but I still would have a high temperature to contend with—a temperature of 104 or 105 I think there is nothing better to relieve that than cold irrigation I have tried sponging the skin and other things, but in a high temperature in a diarrheal disease that is continuous, I strongly recommend cold irrigation of 80 or 85 degrees, and reducing it to 70 If the child seems to collapse under the changed temperature, it might be wrapped in blankets and stimulated hypodermically

Dr Patterson—I do not want to be understood as advocating sulphate magnesium as a cure for summer diarrhea in children The only way, in my mind, to treat these cases is to remove the cause Remove whatever is there and sterilize the food afterward Sulphate magnesium certainly does remove the contents of and empty the bowels As to removing the bacteria, or whatever is in the intestines, we often find children who have a large number of stools every day, and yet this does not remove the hard mass that we find in them and until you remove that mass the stools will continue Therefore, I think anything that will remove the irritating mass will relieve the condition You do not always get rid of the bacteria by the large number of stools

Now, in regard to the bad taste of the drug I do not know, excepting in two or three cases, that I have had any difficulty whatever in giving sulphate magnesium, and I am very sure that I never lost a case even among the most fastidious by reason of the bad taste of the drug It has not any taste in particular It is very sweet I have given it to children who were very much opposed to taking ordinary drugs—drugs of any kind in fact—with mint water, or something of that sort, and they would take it very readily

A word as to the reliability of dispensary statistics As a rule, you can educate mothers up to the advantage of carefully dieting the child The woman that Dr Adams came across in the dispensary must have been very heartless indeed I have had no trouble in the cases that came under my observation to get the mother to boil the milk, by furnishing the means for sterilizing the milk, and have had good results that way I repeat that I do not want to be understood as advocating sulphate magnesium as a cure for summer diarrhea but advocate it as a means of putting a child in the position to get well

HAS TUBERCULOUS COW'S MILK CAUSATIVE INFLUENCE IN TUBERCULOSIS OF INFANCY?

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895

BY FRANK S PARSONS, M D
EDITOR OF THE TIMES AND REGISTER
PHILADELPHIA PA

In the discussion of this subject, two questions enter into it, upon which the etiology of tuberculosis, and the degree of danger arising from the ingestion of tuberculous cow's milk, largely depend

1 Is tuberculosis *solely* dependent on the tubercle bacillus for its development?

2 Is the tubercle bacillus found in the milk of *all* tuberculous cows?

As to the first question, I believe, at the present day, it should be generally admitted that we must look beyond the simple introduction of the so called germ to the system for the production of this disease and recognize a condition that is not inherent in the healthy human organism upon which the development of tuberculosis depends

The absence of this condition precludes the possibility of infection from the germ, because of the absence of a cultivation field

The presence of this condition establishes a reason for great apprehension in regard to the ultimate outcome of the case in which it resides

What is this pre tubercular condition which forms the cultivation field of the tubercle bacillus?

We must recognize that the ingestion of tubercle bacilli does not necessarily result in tuberculosis in the human organism This fact has been proved beyond a doubt by various observers and is one which must be self-evident, inasmuch as all persons must be frequently exposed to the reception of this germ in some manner or other Hardly an autopsy is made without the proving that some time during the life of the subject, tubercles had developed, as evidenced by the cicatricial repair of the parts Cicatricial repair, we know, follows suppurative process and the latter is due to interference with circulation in the part involved In other words, there has been a loss of normal correlation in the afferent and efferent blood supply

For a more minute discussion of the influence of this loss of correlation on the production of tuberculosis, I shall be obliged, in order to prevent a great length to this paper, to refer to an article published by myself in the Philadelphia *Medical Times and Register* which runs through the first five issues of the present year, entitled a "Practical Theory and Treatment of Pulmonary Tuberculosis"

Briefly, however, I endeavored to show, in the article alluded to, that tuberculosis must be dependent on a lymphatic stasis, that said stasis arises from a backing up of waste elements in the blood at the point affected, and, that the production of excessive waste may occur from a deoxidation of blood cells, or a faulty condition of one or more of the emunctory organs, which condition may be congenital or acquired

A stasis, if present, forms a fertile field for the cultivation of the tubercle bacillus and the breaking down of the tissue involved

The curability of the lesion, and secondarily the disease, depends on the facility with which the normal correlation of the afferent and efferent blood supply can be restored in the parts affected, with a removal of the waste, and re oxidation of blood cells

If tubercle bacilli can find no lodging place in the human organism, upon which they can rest to germinate,—a state which implies perfect elimination—no deleterious effect is observed from their intrŏduction into the system

The fact that certain animals develop tuberculosis from the injection of bacilli, artificially, simply proves that such animals are susceptible to the irritating action of foreign bodies by a constitutional construction calculated to develop lymphatic stasis under the slightest provocation

Thus it may be confidently assumed that the tubercle bacillus is a secondary rather than a primary causative agent of tuberculosis

The conclusion to be reached in respect to our first question in its relation to the subject under discussion, it seems to me, must be based on the probability of the existence, or non-existence, of lymphatic stasis in the child who is fed on tuberculous milk, for instance, a child with lymphatic obstruction would undoubtedly develop tuberculosis, or the symptoms of tuberculosis so far as the tubercle bacillus determines it, if he was fed with milk in which tubercle bacilli existed, otherwise he would show no signs of such infection

The second question in our subject depends on the existence of the tubercle bacilli in the milk of tuberculous cows, and relates to the first only as the possibility arises of susceptible children being fed on milk which contains these germs

M Alexandre, in a report on the subject of tuberculosis in the stables of the Department of the Seine, France, holds that the terrible mortality from tuberculosis is not the result of the consumption of milk and flesh of our domestic animals, and that this belief should be thoroughly rooted out of the minds of the profession and laity

The danger of infecting the milk of diseased animals seems to lie in the existence of local tubercular lesion of the udder alone If this be absent, tubercle bacilli are found wanting in the milk of cows, even though they may be suffering from tuberculosis of other parts If no tubercle bacilli are found in the milk, there seems to be no evidence that there is any danger from the use of milk as food so far as the causation of tuberculosis is concerned

In conclusion, it may be stated that, from the evidence obtained up to the present time, there is nothing to show that milk from tuberculous cows is infectious, except in those cases exhibiting a pre-tubercular condition corresponding to that previously indicated, presenting a favorable cultivation ground for the tubercle bacillus, and then only from the milk of such animals as have local lesions of the udder

SOME OF THE CAUSES OF THE GREAT MORTALITY IN INFANCY AND CHILDHOOD

Read in the Section on Diseases of Children, at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7-10, 1895.

BY J. A. WORK, M.D.
ELKHART, IND.

In discussing this important subject we will premise with the unquestionable proposition, viz., that in the main, physical human nature is the same the world over. Thus, conclusions derived from data from any nation, country or clime, with common environments peculiar to the subject under consideration are applicable to all. For instance, the causes that effect so great an infantile mortality in London or Paris, New York or Chicago, also exist to a greater or less degree in all large cities. The denser the massing together of human beings, the greater the multiplicity of causes of disease, and the inevitable calamitous results.

The great variety of habits and customs of a conglomerate of races and nationalities, such as in this age of rapid and cheap transit, makes it almost impossible to prevent any large city from being a fertile field for every conceivable form of disease, and the helpless infant is the easier claimed victim.

By conclusions drawn from data, necessarily incomplete, on account of the very inaccurate records, we learn that about one-half of all the deaths reported in our country, as well as elsewhere, are children under 5 years of age. If the infant comes into this physical existence a perfect being and has the proper environments, there should not be such a fearful mortality. But, alas, perfection is found in neither the infant nor its surroundings. Why is not the infant perfect physically? Answer: very few, if any parents can boast of perfect health. Thus the hereditary taint of disease, or a weakness which predisposes the infant to the numerous dangers which beset its brief life; we say brief, for the facts adduced show that one-tenth of all infants born die in the first month, one-fourth die before the first year is completed, and one-half die before the fifth year is reached. This is an alarming revelation, worthy the due consideration of Christian patriots and philanthropists. Were we to enumerate the principal causes of this dire condition, the low ebb of human vitality, we would thus record them: 1, heredity; 2, inexperience; 3, ignorance on the part of all concerned in the production and care of the infant; 4, zymotic diseases; 5, want of natural affection on the part of parents.

This list, we believe, comprises the principal causes, but probably not all; and some of these may to some individuals seem far-fetched or remote from the subject. But let us first consider heredity. The stubborn facts gleaned from observation and research will not allow us to conclude other than that myriads of infants die of hereditary taint, to say nothing of the myriads that would be born and live, were it not for this blight. Diseases transmissible are not conducive to longevity, but, on the contrary, they so violate the constitution that, if gestation is completed at all, the child by virtue of the hereditary blight can but eke out a miserable existence. This is true of all constitutional diseases, more or less. This is true to a greater degree where successive generations have been affected with any hereditary taint. Truly, "the iniquities of the fathers are visited upon the children, unto the third and fourth generations," and in a less degree where a parent with former vigorous constitution acquires the disease just prior to conception, or the hereditary effect upon the offspring may be a lack of physical development of one or more vital organs, or a weakness of the whole system without any special diseased part. Infants hereditarily affected do not all die, consequently the mortality in the succeeding generations from this too large class of diseased but often physically active beings. Sixty per cent of the mortality of children of healthy parentage could be prevented were it not for the inexperience so prevalent with the class who do not oppose reproduction.

Many parents do not even have the instinct as to feeding their young that the lower order of animals have. They do not seem to know that the infant, as a rule, brings its natural life and health-sustaining food with it, but are ready to feed it all manner of food which manufacturers have been actuated to invent from whatever motive. They know the child's stomach only as a receptacle, and are slow to learn that any food will harm the digestive apparatus, because they (the parents, or perchance the grandmother) are fond of such food. I have known well-meaning mothers to feed their babies mince pie, fried potatoes, all kinds of fruits, meats, nuts and *all* before the child had a sign of a tooth. And when the almost universal rational artificial food (cow's milk) has to be given, such kindness is bestowed that the child gets all that it wants and whenever it wants it, regardless of the impaired condition of the digestive organs. Often food is given where drink, only, is necessarily required by the fretting child. In many instances if not death, irreparable injury is produced by urging children to fill or gorge their stomachs with fresh food, while a large portion of the former meal in a decomposed condition remains. The result of a continuation of this very common habit is obvious to the pathologist.

Too little attention is given to proper clothing during infancy and childhood. Whether asleep or awake, there are always at least two indications to be observed, viz., the clothing should be of a texture to produce uniform warmth, and should be made to produce uniform pressure on all parts of the clothed surface. I have known mothers or nurses to take the babe from a warm bed of blankets and hold it in a cool atmosphere without wraps as warm as the bedding was. Many infants sleep with their parents or nurse, and are compelled to breathe the noxious exhalations of their bodies. Not a few are smothered by this unhealthful habit, and take their place in the vital statistician's list of "accidental."

I once knew a fashionable young mother to begin with the first swaddling band to lace her infant daughter, stating that she desired the child to have a "good form." Alas, before the first anniversary of birth was reached, she had gone to swell the list of deaths by "developmental diseases."

There is a factor which increases the mortality list of children to an alarming degree, which we have reasonable hope ere long, by the aid of the microscope and other inventions in the hands of the scientific investigator, to reduce to the minimum, and take its place as the least to be dreaded of all the causes of death. I refer to the zymotic diseases that play such havoc at times among our promising rising generation, blighting fond expectations.

Sanitation has done more, is doing more, and it is likely will do more to eradicate or at least modify, this dreadful class of causes of death, than can be reasonably expected in relation to other causes mentioned

Early effective elimination as advocated before this Section two years ago, in all the diseases belonging to this class, will rob it of many of its victims and thus materially reduce the mortality list (Please pardon this digression from *cause* to *cure*)

The last cause we will mention is the lack of "natural affection' The divinely inspired apostle to the Gentiles, in writing to his son in the faith (Timothy) thus declaims that in the last days perilous times shall come, and "without natural affection" is one of the morally degenerating symptoms, and we believe it also to have, as well, a physical degenerating effect How many, not *would-be* but *could-be* mothers, manifest more affection for a pug or poodle than for their own offspring? We ask a question that the observing practitioner may answer according to his own experience as a family physician What proportion of all children born are welcome or were wanted prior to conception? If I am left to answer, I will venture the assertion that not more than one-third This may be too low a guess Then think of a mother in constant rebellion during the whole time of gestation, and the effect physically, as well as morally, on the begotten, and if an effect on this, what of the next and successive generations? How many of the unwanted babies are neglected, even unto death, by the thus vicious who give their children the endearing appellation of "kids?" How many mothers in fashionable circles say that they do not want their liberties infringed upon, will not nurse their babes, and thus give them only a chance for their lives? How many carelessly prepare the food for, and as carelessly feed the little helpless creatures? How many desert their progeny? The foundling homes so mercifully provided in many of our large cities do witness of this shame, of the lack of natural affection Infant insurance will find a hearty support in this class of misanthropists

Much more could be said by way of pointing to the causes of the alarming mortality of infants, but we will content ourselves if enough has been said to elicit a proper sense of the responsibility we should feel in our chosen profession May we prove ourselves not only worthy the name Physician, but Philanthropist as well

300 Division Street

HEREDITY AND ITS ENVIRONMENTS

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7 10 1895

BY J E RIGG, M.D

WILKINSBURG PA

When a child is born we may well ask what heritage it brings, from whence did it come, and what influences in the history of its ancestors would modify its condition to resist the evil influences which will surround it through life?

The late Dr Holmes said, "that if we would properly educate a child we must begin 300 years before its birth " If this be true with reference to education, is it not much more true with reference to a healthy and perfect organism being given to the child, that it may be the better able to resist diseased influences and unhealthy surroundings

The most important predisposing causes of disease are those connected with the structure of the body, having individual peculiarities, which may be inherited or may be congenital In most of the so-called hereditary diseases, that which is transmitted from parent to child is not the disease itself, nor its direct specific cause, but some peculiarity of structure of tissue or organs which, in the course of development either make the person peculiarly susceptible to diseased action from without, or produce disorders itself by defect of structure or function of some particular part

A person is said to possess immunity as regards a certain disease when he is but slowly, or not at all, affected by the causes of that disease when brought into contact with it Immunity may be natural or artificial, partial or complete Natural immunity may be hereditary, as for example, the insusceptibility of the negro to malaria and yellow fever Artificial or acquired immunity may be produced by the action of the disease itself, as in smallpox, scarlet fever, measles, whooping cough, etc , and also from smallpox by the proper vaccination with the kinepox lymph Precisely how this immunity is produced we do not know, but it is probably due to the presence of certain albuminoid substances which have the power of killing or weakening the pathogenic microorganisms or neutralizing their toxic products Immunity is rarely absolute and complete

It has been asserted that children born of syphilitic parents are protected against syphilis

Experiments on animals and observations on human beings have shown conclusively that infectious agents may pass from the mother to the fetus through the placenta, as has been observed in smallpox, measles, scarlatina, relapsing fever and syphilis

It is asserted by Baumgarten that the tubercle bacilli may be transmitted in this manner This view is not, however, generally held The generally accepted views are that the condition or predisposition to the subsequent development of tuberculosis is inherited This condition, Formad asserted to have been particularly marked in children with narrow lymph spaces

It has been claimed that heredity plays an important part in the etiology of aneurysm, chlorosis, diabetes, emphysema, goitre, gout, rheumatism and rickets

There can be no question but what the condition of the parents has something to do with the health and strength of the child, which receives its start in life from their union Lead poisoning on the part of the father is thought to lessen the vital force of the offspring

Dr Hirst has stated that out of thirty-nine pregnancies in women whose husbands were sufferers from chronic lead poisoning, eleven ended in abortion, one ended in stillbirth and only nine survived early infancy

The influence of syphilis in the parent on the fetus, and subsequently on the child, is too well known by this body of scientific men to require any argument

Drunkenness also plays an important part in the health of the future generation A man may claim that he has drank whisky all his life and is yet in a good state of preservation Such may be the case, but to see the full effect of his habit, look at his children, and we find that they will not compare favorably with those whose parents have not been given to strong drink.

In the hospital for children at Berne, Switzerland, it was found that only 45 per cent of children born of intemperate parents enjoyed good constitutions, while 82 per cent of those born of temperate parents enjoyed that blessing.

The union of two persons of the same temperament often results in children with unbalanced constitutions. That is, that particular temperament leads so strongly, that the child is overdeveloped in that particular line and does not reach the standard in others. The result is a diseased constitution. Also the union between certain nationalities seem to have in some instances an unhealthy effect. Same facts bearing on this were found by the writer while collecting statistics in Westmoreland County, Pennsylvania, in 1884. It was found in one part of that county that the early settlers had been Swedes, who were a healthy thrifty class. Near by was a community settled shortly after by the Irish, who also had a good family record. Tuberculosis was not known in either settlement. Later, perhaps in the third generation, they mingled together and a number of marriages occurred. In each case tuberculosis was found in some of its forms. A close inquiry failed to trace it back on either side. Those who married among descendants of other nations were not so afflicted.

The manner of living may have much to do with the proper nutrition of the growing cells. One instance will serve to illustrate this point. A father and mother of very good family history lived in a stone house built on a hillside, the first floor being partly under ground, and this was the part mainly used by the family. In this house they raised their family consisting of seven children. Four died before the age of 25 of tuberculosis, one at about 35 and one at 45 of the same trouble, one only living to die of cancer at the age of 50 years.

For at least three generations back the family history was good. On the one side they were of Irish descent, on the other side, I could not learn of what nation they had come.

The mental condition of the maternal parent must produce some impression on the child. How, we do not know, as so far there is no direct connection between the nervous system of the mother and the fetus, but the facts stand well established that there is some unknown force, the influence of which must be recognized. The case of Jesse Pomeroy stands not alone in support of this theory. The sieges of Lucknow and of Landau furnish additional proof of this.

As a chain is strong only at its weakest point, so we are only strong at our weakest cell.

Anything that will cause cell life to be at a low standard will, in some way or other, so weaken our forces that we will be less able to resist the influence of disease, as well as retard our growth and give us a body which will be beneath that of our neighbor who was brought into the world under less unfavorable circumstances. We must not stop when the child is born, for there are many influences which will change for better or worse the power of resistance and vital force of the physical organism of the infant with which it will have to contend in its march through life. These are most usually found in the diet which it receives and the care with which it is guarded from colds and exposure and the care that is exercised in giving it good air and plenty of sunshine.

As to heredity, it is important that each parent should exercise great care to see that they are free from any taint of disease, either inherited or acquired, and that they are not overworked physically or mentally. As to the liability of overwork physically, that is not so likely, but from a mental standpoint the reverse is true. In this age of rush and push among our American people, there is great danger of the nervous system being so exhausted by the strain of business and the desire for place that there is no power left to give vital force to the germs that are to develop into the future being.

It is the writer's belief that were it not for the introduction into our race of the slower and less nervous class that we would degenerate more rapidly than we do. This may be putting it strongly, to imply that we are in a state of degeneration, but it is surely true that we are living at too fast a pace and the laws of self-exhaustion will in time weaken and impair us to such an extent that we will no longer be able to hold our place as a nation and people.

Is it not time, then, to give the alarm? And from where is this warning to come if not from the physician? Let us give timely advice to those who intrust their health and lives in our hands. Let us not fail to look to their future good as well as their present protection. Take, for instance, a child that is born of parents who have exhausted their vital powers in their pursuit after wealth and society. Their child is given, as a heritage, a highly developed nervous system. It is raised on the bottle and its care is given to a nurse who has neither knowledge or judgment to guide her. She seeks her own comfort and not the health of the child; she allows it to be in drafts, to remain in damp clothes, to have its food whether fresh or stale. The child will suffer first from cold, then from excessive heat. What is the result? Bronchial troubles develop and carry off many, the stomach and bowels become diseased and the child lingers between life and death for a season and then slowly recovers. What is the effect of this prolonged perversion of cell nutrition? It must be to weaken the cell life of each and every cell of which the body is composed. Suppose this child be a girl. She is placed in school at an early age and is expected to accomplish by the time she is 18 as much as ought to be expected at 24; but she must be through school and enter society at 18 or, at most, 20, and what is her condition? Alas, too often so broken in health that she can only attend to her social duty and then under the stimulating lash of social rivalry. Yet she is expected to marry in a short time and give strength, force and character to her offspring, none of which she herself possesses.

How, then, are we to protect our children from the evil influences from which they suffer and for which they are in no way responsible? By prohibiting improper marriages, by teaching the proper care of the body on the part of both parents, and by limiting the amount of nerve force expended by them during the period in which their children are conceived and brought forth; by the proper care of the infant in regard to its food, clothing, rest, fresh air and clear sunshine; by guarding it from extremes of temperature, protecting it from drafts and in every way keeping it in a regular line of life, and when it comes to the proper age to go to school, to see to it that the building is well ventilated without pushing up the windows at the back of the child that air may rush in and chill the little frame already weakened by bad air and too close application to its books Then, as it grows older, especially if it be a girl, say 13 years of age, let the next two years be spent in the development of the body rather than forcing the mental training, as at this age the system needs all the nervous force and vital energy to establish the normal functions of the body We should also place our public schools under the care of intelligent and careful men and women who are competent to care for the body and mind

---

BROMOFORM IN PERTUSSIS

Read in the Section on Diseases of Children at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895.

BY P J EATON, A M, M D (Harv)
PITTSBURG PA

I wish to bring to your attention the results of some studies I have recently made upon bromoform, its chemistry, pharmacology, and therapeutic action in certain diseases

Bromoform is a colorless liquid of sp gr 2 83 at 0 degrees C, and is represented by the symbol $CHBr_3$ It is produced by the action of bromin upon alcohol in the presence of an alkali In practice, milk of lime is saturated with bromin, alcohol is added, and the mixture distilled The resulting liquid is colorless, sweet to the taste, and gives the sensation of burning Its physiology may be summed up in saying that it is an agreeable anesthetic, without danger, merely lowering blood pressure, a narcotic when used hypodermically, and, finally, is an antipyretic The excitability of the psychomotor centers and the general reflexes are entirely abolished when anesthesia is complete The urine contains bromin some hours later

In leading up to the discussion of the value of bromoform in pertussis and certain other forms of spasmodic cough, and in referring to the methods of administration, and manner of its exhibition, I shall report briefly some cases in which the drug was used, and from these cases hope to deduce some points of interest

Cases 1 and 2—Father and son Middle aged, and 6 years old respectively Came to me Nov 12, 1893, with the history of having had whooping cough since spring They had tried many doctors and much medicine with no benefit Both pale, and pretty well worn out Gave bromoform in appropriate doses, and in ten days patients both reported themselves well

Case 3—Boy fifteen months of age Began to whoop July 25, 1894 Had not been very well for some time, having had some intestinal indigestion Began bromoform at once, drops 2 to 3, four times a day On the third day he was stupid, temperature 101.3 degrees, anorexia malaise Reduced the dose of bromoform for a day or two to 1 drop, occasionally omitting a dose Then increased it, as cough was rapidly growing worse He then took 6 drops without any bad symptoms By the middle of August he had stopped whooping, and on August 29, I have record of very rapid improvement He has had one bad cold since, during which he whooped a few times He is now, Nov 26, 1894 in robust health

Case 4—Spring of 1894, boy 3 years of age Mild case Bromoform given early In seven or eight days ceased whooping Coughed some time longer During the summer he had one or two colds, and would give a mild whoop occasionally General health suffered very little

Cases 5 and 6—Brother and sister, 8 and 10 years of age, summer of 1894, both took bromoform well, the boy recovering in ten days, the girl in two weeks The boy had a light attack, the girl a pretty severe one Both had whooped a week before having any treatment

Case 7—Middle aged gentleman, summer of 1894 He had had pertussis when a child He is father of Cases 8 and 9 Took rapidly increasing doses up to 30 drops with relief, but not complete cure He was very much racked by the paroxysms A sea trip from Boston to Baltimore, and continuance of the drug cured him within a week Coughed in all, three weeks

Cases 8 and 9—Four-year old girl and 1 year old baby Bad cases The older child would not take the medicine well and was only relieved The baby was taken to sea, and greatly benefited Bromoform was not pushed to physiologic limits in either case

Case 10—Summer of 1893, girl 4 years of age Mother would not give medicine regularly, and child did not improve She coughed all summer

Case 11—1892, boy 3 years old He whooped for a week or two before beginning treatment Was seen twice at intervals of three days Marked improvement One day at about 1 P M, his mother discovered the bottle of bromoform which had contained 1 drachm, about half empty The boy denied having taken any He was brought to my office about 2 15 P M I could smell no bromoform in his breath, and he was as bright as usual About 6 P M I was summoned by telephone and found on my arrival, that the boy in running to meet his father about 5 50 P M, had suddenly grown very sleepy and stupid, and soon had become comatose Hypodermics of ether and whisky and hot enemata were given for flagging pulse Friction to cold extremities was used, and pricking and slapping to keep patient awake In an hour he was out of danger Slept heavily during the night, and the following day was as well as usual No more bromoform was given, but the attack passed away very soon

Case 12—Summer of 1893, boy 8 years old Had been whooping hard for three weeks and was pretty well used up Made out a schedule for a week's treatment I did not see the boy again but met his mother on the street ten days afterward She said she had not brought the boy to the office as requested because he had ceased whooping at the end of five days, and was perfectly well at the time of our interview

Case 13—1893, girl about 5 years of age Gave bromoform in increasing doses up to 17 drops with relief but no very marked or prompt cure I did not dare to give any larger doses The attack lasted about four weeks A sister two years older was greatly benefited by the drug, and was well long before Case 13 Her maximum was 11 drops Both children were singularly quiet and deliberate in their actions and very phlegmatic

Case 14—June 8, 1894, male, eighteen months of age Coughed for several days Dose, 2 up to 4 drops A mild attack Well in a few days

Case 15—June 3, 1894, female 3 years of age Coughed for several days Dose, 3 up to 6 drops Moderate attack Began to diminish dose June 17 1894 Was well in two weeks

Case 16—June 12, 1894 female 25 years of age Was sick several weeks Dose 6 up to 18 drops Stopped whooping on June 22 Slowly diminished the medicine

Case 17—June 12, 1894, female 2 years of age Was sick several weeks Dose, 2 up to 4 drops Moderate attack On 23d was well of cough

Case 18—Dec 11, 1893, female sixteen months old Was sick two weeks Dose, 2 up to 4 drops Mild attack On December 23 was well

Case 19—Sept 6, 1893, female 26 years of age Coughed for a week or two Dose, 6 up to 20 drops Very severe attack By 16th much better, on 19th only one whoop Then diminished bromoform

Case 20—Sept 6, 1893, male 3 years of age Coughed for a week or two Dose, 3 up to 6 drops A moderate attack. Was well in ten days, except little loose cough

Case 21—Spring of 1894, male 8 years of age Had cough and cold for a few days Dose, 4 up to 9 drops Had rather severe attack Was well in three weeks

Case 22—Spring of 1894, female 5 years of age Had cough and cold for a few days Dose 3 up to 7 drops Mild attack Was well in two weeks

Case 23—Spring of 1894, female 6 years old Onset rather abrupt Dose, 4 up to 7 drops Mild attack Was well in ten days

Case 24—Spring of 1894, female 3 years of age Had catarrhal cold for a week Dose, 3 up to 5 drops Mild attack Was well in twelve days

Case 25—November 1894, female 6 years of age Whooped three weeks before treatment Dose, 4 up to 9 drops Severe attack Well in two weeks

Case 26—November, 1894 female 4 years of age Had whooped three weeks Dose, 3 up to 12 drops Very severe attack Was well in three weeks, and grew rapidly very fat

Case 27—November, 1894, female 2 years old Whooped for ten days Dose, 3 up to 5 drops Severe attack Well in three weeks

Case 28—November, 1894, male 2½ years of age Dose, 2 up to 4 drops Mild attack On the fifth day caught cold Temperature 104 degrees Dull, stupid, languid I stopped bromoform and gave aconite and belladonna In two days resumed bromoform Now, whooping about once in two days and sleeping and eating well, and coughing much less

Case 29—Exposed Oct 22, 1894, boy eight months old Coughed from the 20th to the 28th quite violently, and on the evening of the 28th whooped from twenty to thirty times —typically I gave 2 drops of bromoform at 8 P M, and at 1 A M Temperature normal, pulse 120 Did not whoop after 11 P M until the next day at 7 A M, two whoops, 7 30, 2 drops of bromoform Temperature and pulse normal At noon, 3 drops bromoform, at 4 P M 2 drops One whoop at 1 P M., 6 P M, temperature 99 4 degrees, pulse 120, good Much swallowed mucus in stool to-day Dull and sick—that night whooped once Slept well

October 30 No whooping to day Cough loose and very moderate Gave 5 drops of bromoform during the day Evening temperature 99 2 degrees, pulse 120

October 31, slept well Bright as usual Coughed several times—no whoop—ate well Temperature and pulse normal

November 1 Gave 1 drop of bromoform four times to-day No whoops

November 15, an occasional cough No more whoops

Shortly after last record, baby caught cold and coughed several times a day No whoops Has gained steadily since

My plan of administration is based on the following idea begin with a dose which can be well borne, increase as rapidly as is compatible with safety up to the maximum dose, *i e*, that dose which distinctly diminishes the number and violence of the whoops As the number of paroxysms decidedly lessens, and when the patient sleeps all night, I begin to diminish the dose by drops I give it four times a day as a rule, but in severe cases add an extra dose in the middle of the night I see the patients frequently, and keep close watch on the *condition of lungs, bronchi and heart* I have always exhibited bromoform in its pure state, writing for a given quantity of the drug and ordering it to be put up in a dropping bottle, and to be given in a little water, this I do because it can not be easily dropped in any other way If you bear in mind the high sp gr, you will understand why it is difficult to drop, and you will not be surprised to know that there are in the neighborhood of 360 drops in one drachm

Mr Geo W Hackney, Ph G, of Pittsburg, has made, at my instance, many experiments looking toward some other and more agreeable method of giving this drug His work seems to show that emulsions are not palatable, that mixtures are not safe, and that the best way, outside of my own way of giving it in water, is in a mixture of alcohol, glycerin and water

The first requisite seems unattainable, each mixture or solution seeming to markedly retain the sweet pungent taste of the drug The second requisite, that of safety, obtains only in absolute solutions—alcohols of various strengths

I have made it a practice to repeatedly examine the heart and lungs of all cases, and the record has been here omitted only to insure brevity In no case under observation was there any heart lesion developed, nor was there any moist râles, except in two cases These cases differed in severity, but Cases 16, 19, 21, 25, 26 were certainly very severe Case 26, for example, having, previous to treatment, lost her breakfast eight times in one morning

Since I wrote the body of this paper, Dr W W Johnston, of Washington, has, in the *Archives of Pediatrics* (April, 1895), called our attention to the great mortality in pertussis His essay deals with the shadowy side, and we are indebted to him for his exhaustive comparisons and mathematical data He deals with things as they *are* and *have been*, and not as they *may* be I do not want to precipitate a discussion on pertussis as a disease, but only to call to your attention the fact that in the use of bromoform we have a method of controlling this disease and avoiding the great mortality which surely does obtain

There is another class of cases to which I wish briefly to refer, in which bromoform seems to accomplish something unattainable in any other way I refer to those bronchial subacute colds in adults, in which a very hard, persistent, dry cough obtains, and which seem to resist the drugs ordinarily given for their amelioration In such cases I have found bromoform to work most effectively, in a very short time reducing the frequency of the cough, causing a moderately free expectoration, and consequently relieving the muscular distress of the patient To such cases I give the drug in capsule (letting the patient fill the capsule) in doses ranging from 20 to 30 drops every six hours

The danger signal is usually plainly to be seen, drowsiness following the exhibition of an overdose, usually in course of an hour or two

In conclusion, let me again lay stress on my method of giving this drug, viz begin with a known safe dose, then push to the limit of evident relief of symptoms as rapidly as possible In this way we may expect to avoid many of the complications and save much time in the treatment of this disease—as well as markedly reduce the mortality

---

DOUBLE CLUB FEET AND HANDS—TREATMENT

Read in the Section on Diseases of Children at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10, 1895

BY B MERRILL RICKETTS, M D

CINCINNATI

The object of presenting this subject and report of a case is to place one of the rarest affections on record, and to draw from its history and treatment any deductions that may be of profit

It is to be regretted that so little has been accomplished, especially in rendering the club hands more useful

Unfortunately, the causes do not lie within the domain of surgery—they being manifested in utero

Whatever the cause may be, the results are practically the same, if it is due to a neurosis, but little can be hoped for in increasing the usefulness of the affected extremity

If, however, the nerves should not be affected, and the deformity due to an over- or under-developed bone, the greatest benefit usually ensues from some surgical procedure

There is a condition found in the congenital paralysis of the extensors of the forearm which does not exist in the congenital paralysis of the extensors of the lower leg, viz, the ankylosis of the elbow joint This seems invariably the case

I have not thus far been able to find any report of ankylosis of the knee joint in paralyses of this nature

On the other hand, the joint motion of the knee is nearly always perfect, this may be accounted for by there being but one movement in the knee—the backward and forward one, we have beside this motion in the elbow, a rotary motion which renders the hand capable of abduction and adduction

These two movements are greatly lessened when the hand is flexed to the extreme, as in case of club hand This prolonged flexion in utero results in ankylosis, and the arms having less strength than the legs are more likely to remain quiescent

The arms are drawn forward, giving a narrow appearance to the chest, but the shoulder movement is usually good

Some if not all of the carpal bones are always changed in their shape as the result of prolonged affliction at a time when they are very soft and easily molded There may also be one or more absent

The second finger is usually very much flexed and overlapped by the index and third fingers The thumb is drawn across the palm and pain is experienced when it is brought into a normal position

Male, age 10 weeks well nourished Has four healthy brothers and sisters, congenital Extensors do not respond to either faradism or galvanism interrupted or straight Multiple neuritis of tibial and radial nerves Cut both tendo-Achilles and tendon and plantar fasciæ of both feet Applied plaster-of Paris massage, etc great improvement.

Multiple neuritis of the nerves supplying the affected muscles is usually found, but just what produces multiple neuritis remains a question In the case I present for your consideration, no cause can be assigned

The child, a male, white, was ten weeks old at the time that I first saw it, Jan 10, 1894, when it was placed in my private hospital for observation A consultation with Dr Phillip Zenner resulted in finding the subject well nourished, and the youngest of five healthy children The extensor muscles did not respond to either faradism or galvanism, interrupted or straight current It was found that there were multiple neurites of the tibial and radial nerves The bones of the two upper extremities and the left lower, including the tarsal and metatarsal, carpal and metacarpal, seemed to be normal in shape and number, also the bones of the right leg and foot, except the phalanges All of the toes of the right foot were imperfectly developed, while the tarsal and metatarsal bones seemed, as far as could be determined, as perfectly developed as those of the left foot There was, however, a slight curvature of the right tibia, and the talipes was of a higher degree Massage and light brass splints of my own construction were applied to the foot These were kept on for fifteen or twenty days at intervals of three or four days each, during these intervals vigorous massage was applied, each tendo-Achilles was divided, after which the normal condition was more nearly reached During this time, the mother was taught to extend the hands and massage freely The fingers were extended separately and collectively, and I must say that during the three weeks of treatment the improvement was much more than I had expected

The mother returned to her home after the third week and continued the treatment under the direction of Dr E S Buffington

About May 20, 1894, I again divided both the tendons and plantar fasciæ of each foot, which enabled them to be placed in a better condition than on any previous occasion

The extremities were bandaged with plaster-of-Paris, which was allowed to remain for ten days, at the end of which time it was found that the position of each foot had been greatly improved

The mother continues massage of the feet and hands, and the patient gradually secures better use of them

DISCUSSION

Dr Manley, of New York—This is a matter which must command particular attention on the part of those whose specialty is dealing with the diseases and deformities peculiar to very early life, and in connection with the subject which the Doctor has presented, the question arises, and upon which I hope the members here who have had experience in that class of cases will express themselves, as to whether it is the proper thing at an early stage in life, before the child is weaned and before it has begun to walk, to endeavor at once to radically overcome those deformities, or whether it is better to treat them by a gradual process of manipulation with appliances which will overcome the tendency to those spasmodic inclinations, and try to attain the end in view by massage and electricity

I must say that so far as my own experience goes, particularly in these cases of talipes varus, by a division of the tendo-Achilles, not only the correction, but hyper correction of the ankle of the foot, to keep the limb in that form until the spasmodic tendency is overcome, is usually done early I do not gather that in this case there was any history of heredity as to deformities in any of the ancestors of the child I simply wish to say that the deformity of the hands produced by action of the same or analogous set of muscles as in the legs, is quite unusual, and I think gentlemen here are interested in seeing the extent of correction the Doctor has effected in this very interesting case

Dr Ricketts—I am thoroughly convinced that the best means sometimes are the most radical, and that the best results are obtained only by the most radical means In this case, as in many cases of club feet and bow legs, I believe in a child it is best to put it in a condition whereby it can get upon its feet as soon as possible That is why we have better results in this condition of the feet than we do in the hands If we could go back to the period when we were quadrupeds, and put the weight on the hands that we do on the feet, there would be no reason why the hands should not improve in the same degree as the feet The question comes up in this case as to what is the best way of treatment The feet are improving rapidly, the hands are improving also, but as I stated in the paper, the improvement in the hands is much less than the improvement in the feet, for the reason, perhaps, that the weight of the body adds materially to the good influences in correcting the deformity of the feet This is the sixth case, I believe, that has been reported in this country, so far as I can ascertain Dr Reginald, about two years ago, reported five cases of this character, and I have since learned that this is about the sixth case reported thus far in American literature

PELVIC DISEASE IN WOMEN, AND INSANITY

Read at the Fifty-first Annual Meeting of the American Medico Psychological Association, at Denver, Colo., June 13, 1895.

BY GEORGE H. ROHÉ, M.D.
SUPERINTENDENT MARYLAND HOSPITAL FOR THE INSANE
CATONSVILLE, MD.

At the meeting of this Association in 1892, I reported, briefly, the results of my experience in operating upon a small number of insane women suffering at the same time from disease of the pelvic organs. This report was afterward supplemented by more extended and specialized papers read before the American Medical Association, and the American Association of Obstetricians and Gynecologists. The work has attracted some attention, and has given occasion for favorable comment and unfavorable criticism. In one instance, a laudable endeavor at imitation was rudely suppressed by the official interference of a State Commission in Lunacy whose *obiter dictum*, that operations upon the insane were "brutal and inhuman, and not excusable on any reasonable ground," as well as "illegal and unjustifiable," received the indorsement of some of the most distinguished members of this Association.

Whether the opposition to the work referred to, can be justified upon medical and surgical grounds, I shall examine later on. For the moment, I desire to invite your attention to the legal aspect of the matter, for if the assertion of the Pennsylvania Committee in Lunacy, that a surgical operation upon a lunatic is in all cases "illegal and unjustifiable," is correct, the sooner physicians and surgeons in attendance upon the insane know it, the better for themselves, although it might not be to the advantage of their patients.

I have devoted a good deal of time and attention to the investigation of this point. In the first place, it was desirable to ascertain what, if any, specific legislation bearing upon this matter existed. My own reading, as well as the experience of several eminent lawyers consulted, failed to disclose any statutory enactment governing the authority of a medical attendant to decide upon the necessity of a surgical operation upon a lunatic.

A priori, a surgeon acting in good faith, and for the benefit of his patient, might therefore perform an operation upon a lunatic without committing specifically, an act contrary to law. Of course it is a general principle of law, and this has found expression in specific enactments, that no one can *in invitum* be even touched by another. And this is held to prohibit the performance of a surgical operation upon a person without his consent. Decisions declaring an operation illegal if the consent of the patient has not previously been obtained are upon record. On the other hand, courts have generally held that this principle is not applicable where it could be shown that the operation was performed for the benefit of the patient.

So far as this legal principle has a bearing upon the performance of surgical operations upon insane persons, it is manifestly confined to the question of what constitutes valid consent. It has been held that a lunatic can not give such consent, and that no other person can give consent for the lunatic. On the other hand, the opinion is held that under certain circumstances, the insane individual is competent to consent to a surgical operation, and that the power to do so may likewise be delegated by a court of equity to the committee of the lunatic. The latter opinion is manifestly the more reasonable one.

The following propositions may be accepted as based upon the principles of law and judicial decisions governing the question of consent by a lunatic to the performance of a surgical operation.

1. The act of a lunatic, during a sane interval, has in law the validity of a sane person; therefore a lunatic, in a sane or lucid interval, is as competent to consent to a surgical operation of any kind as is any person.

2. The State, acting through courts of equity, is the guardian of all insane persons. The equity court appoints a committee as its agent for the discharge of this duty. Such committee is the legal guardian of the person and has the power to consent to such measures as may be for the lunatic's benefit. The committee of a lunatic has, therefore, the power to give consent for the performance of an operation upon the lunatic, if it should be for the latter's benefit.

3. The lunatic may, even if there is no absolutely lucid interval, be competent to give consent to the performance of an operation, if he understands its object and consequences. It is the central principle of the modern law of insanity that the validity of any act of a lunatic depends upon his capacity to perform the particular act in question. Thus it has been decided that a lunatic is capable of being a witness, although not capable of entering into a contract. The law would probably not exact so high a capacity in a lunatic to consent to a surgical operation as it would to enter into a contract. In these cases, however, the physician or surgeon must assume the responsibility of determining whether the lunatic has that degree of capacity requisite to consent. Manifestly, the surgeon is here placed in a delicate position, but one from which, in emergencies, he has no right to shrink. In all cases of doubt, where practicable, the authority of the equity court or of the properly appointed committee should be obtained. The law therefore, so far as it is applicable here, indicates the nature and sources of consent to a surgical operation in an insane person. The further question whether certain methods of treatment are justified—in other words, whether they are necessary or are for the benefit of the insane person remains to be considered.

Every one will agree that any person suffering from a local disease should receive treatment for that disease, irrespective of whether the person is sane or insane. Thus patients with acute infectious or inflammatory disease, disorders of digestion, affections of the heart, lungs, kidneys, surgical diseases, etc., would all receive appropriate treatment for the local morbid condition in all properly conducted insane hospitals. It has become customary in many institutions for the insane, to subject all patients on admission, or soon thereafter, to a physical examination. In this way it has been discovered that a considerable proportion of insane persons suffer from gastro-intestinal disorders, tuberculosis, heart affections, kidney diseases, etc. There seems however, still a widespread prejudice against examining the pelvic organs of insane women to determine the presence or absence of local diseases in the genital organs and pelvic viscera. The failure to make such examination, systematically, is doubtless responsible for the opinion current among asylum physicians, that pelvic disease is rare among female lunatics. I have been told by asylum physicians in this country and abroad, that pelvic disease must be rare among their female patients, because so few of these complain of symptoms referable to the genital sphere. Might I ask, how many cases of cardiac disease would be discovered if the physician waited for the patients to complain of disordered action of the heart, or of the kidneys? Has it not occurred to some of those here present to find an over distended bladder in a male patient when no complaint of local pain or discomfort had been made? I venture to say that systematic examination of the pelvic organs by one familiar with modern methods of examination would disclose a large proportion of pelvic disease among female lunatics. My own examinations in the Maryland Hospital have shown that fully 60 per cent of the women admitted have some lesion of the genital organs or pelvic viscera. Many of these are of so slight a character as to require no treatment, but others can only be relieved by some form of operative interference. Thus, of the affections I have frequently found, are rupture of the perineum, abscesses, cysts of the vulvo-vaginal gland, lacerated cervix uteri, catarrhal and purulent endometritis (usually following puerperal septic conditions) cancer of the uterus, fibroid tumors of the uterus, salpingitis and ovaritis, pyosalpinx and ovarian abscess, cysts of the ovaries and of the broad ligament, and pelvic peritonitis. Defective development of the external genitals has often been found in that class rather vaguely termed "degenerates." In a certain proportion of cases the diagnosis of masturbation can also be made with certainty by the physical examination.

The objection that a vaginal examination directs the attention of the insane patient particularly to the sexual organs, and in this way has a bad moral effect has, according to my observation, no validity. Most patients can readily be examined without an anesthetic, although in some the examination can be more satisfactorily made under anesthesia. Only once in upward of one hundred examinations did the vaginal examination produce an orgasm. This patient was suspected of masturbation, although she had never been detected in the act. The examination disclosed the elongated nymphæ so characteristic of the constant practice of this vice.

If it is true that pelvic disease is prevalent among insane women (an assertion easily confirmed or refuted by further observation) the question arises, Has the pelvic disease any etiologic relation to the mental disturbance? Upon this point, much more extended clinical observation is desirable. I incline to the belief that there is such an etiologic relation. But my experience is as yet too limited to establish this opinion as an axiom. The personal equation which governs every observer's work has not yet been determined. Others, with the same material might arrive at different conclusions. But no one has a right to deny the accuracy of my observations, or the validity of my inferences, unless upon a similar basis of personal experience. I refuse to recognize the authority of any critic "up a tree." He must come down from his perch and meet facts with facts. Arguments based upon prejudices will not answer.

I have expressed my belief in the causative relation of pelvic disease to insanity in women. The mere coexistence of pelvic disease and insanity in women does not establish such a relationship. The cure of the mental disturbance by removing the physical disease, would generally be accepted as a sufficient test. Unfortunately, a cure of the mental derangement does not always follow removal of the local disease. A little reflection will show that there are abundant reasons for this. The brain organization may have already been so much deteriorated by the persistent reflex irritation from the local disease, that local *restitutio in integrum* fails to restore the normal functioning power of the cerebrum. The habit of morbid action of the brain may have been so strongly impressed upon that organ that the original cause of the derangement is no longer necessary to keep it up.

As a contribution to the clinical material upon which eventually any satisfactory conclusion must rest, I shall report in brief my experience during the past four years in the Maryland Hospital for the Insane.

One hundred women were examined, in forty of whom the local lesions found were believed to justify operation. In thirty of these, abdominal section with removal of the uterine appendages, was practiced. In two of these, a subsequent abdominal section was done for the relief of distressing local symptoms. In one, peritoneal adhesions were separated, and in the other a small hematoma was found in the stump of one of the tubes, probably some ovarian tissue had escaped removal at the first operation. The symptoms were pain, metrorrhagia and uterine catarrh. In three of the thirty cases, a secondary vaginal hysterectomy was done. Two of these had already been subjected to a second laparotomy. One of these was finally cured, both of the local symptoms and the mental disturbance. Two cases were subjected to primary vaginal total extirpation of uterus and appendages. In two, repair of lacerated cervix was done. In six, the guardians of the patients would not consent to operation. Of the thirty abdominal sections, there were cured physically and mentally, ten; decidedly improved, four; unimproved, thirteen; died, three.

Of the three secondary vaginal hysterectomies, which are included among the thirteen unimproved after removal of the appendages, one was cured and two remain as before. Of the two primary total extirpations, one was cured and the other so much improved as to give strong hope of ultimate mental recovery. The two trachelorrhaphies both recovered, mentally and physically.

The final results of the operations at present are therefore cured (physically and mentally), fourteen; improved, five; unimproved, twelve; died, three. Total, thirty four.

I have frequently been asked, In what class of cases is an operation indicated? My answer always has been, Where there is local disease discoverable on examination. The mental symptoms, themselves, are no guide. Mania, melancholia, confusional insanity, hystero epilepsy have all been cured. The same forms of mental disturbance have sometimes not been benefited. In consecutive dementia and in epilepsy, where brain deterioration has already occurred, no improvement can be looked for in the psychic symptoms. I believe that in some cases of epilepsy, where there is pelvic irritation, an early removal of the source of the irritation would be of benefit to the patient. In all cases, however, where local disease exists, appropriate treatment is indicated, irrespective of the mental condition Thus, all three of the cases who died were of dementia, two consecutive to epilepsy In all of these there was abundant local disease to demand interference In one, there were large pus tubes and ovarian abscesses matting all the pelvic organs into a mass infiltrated with pus In another, there was an intra-ligamentous cyst as large as an orange The third case was an especially interesting one The patient was a young colored woman suffering from a second attack of insanity, the first outbreak having occurred in 1884 No accurate history of her symptoms could be obtained When admitted in 1895, she was in a state of dementia On physical examination she was found to have a large tumor in the abdomen, which simulated an ovarian cyst, although no definite diagnosis was made On opening the abdomen a large fibroid tumor was discovered, fed by a multitude of large blood vessels from the omentum Some of these vessels were as large as a finger, and one was so large that in its collapsed state it resembled somewhat a section of small intestine The tumor was not connected with the uterus or any of the other solid organs of the abdomen or pelvis It was adherent over a space, as large as the palm of the hand, to the abdominal wall on the left side, and suspended from the omentum through the blood vessels penetrating it from the latter structure The vessels were so friable that catch forceps would tear out as soon as applied The hemorrhage from the tumor, (which was so soft that the finger penetrated it with ease), and from the fragile blood vessels was terrific As the bleeding could not be arrested with the tumor *in situ*, the incision was rapidly enlarged, the adhesions between the growth and the abdominal wall separated with the hand, the tumor turned out of the belly and the vessels stripped off The latter were then tied in mass ligatures in three sections, including as much omental tissue as possible, to prevent the ligatures cutting through the friable vessel walls Three smaller fibroids were then enucleated from the uterus, and the appendages removed The abdomen was thoroughly flushed out with hot water, two gauze drains inserted, the wound closed with silkworm-gut sutures and the patient put to bed

The shock and loss of blood were, however, so great that in spite of the subcutaneous infusion of saline solution the patient died an hour and a quarter after removal from the table The tumor weighed nine and a half pounds and had probably been a pediculated uterine fibroid which finally became separated from the uterus One of the smaller growths removed had also a very small pedicle and would probably in time, had the patient lived, have become separated from its point of attachment

Twelve of the recovered cases have been discharged and all but one are alive and, so far as I have been able to ascertain, remain in physical and mental health Two are still under observation in the hospital

Of those noted as unimproved after operation, two have since died of tuberculosis, that fatal scourge of all institutions for the defective classes In no case has the operation seemed to make the patient worse

The clinical variety of mental disturbance in the recovered cases was puerperal insanity (mania), four, melancholia, six, mania, three, hystero-epilepsy, one Total, fourteen

In the cases in which complete recovery did not follow the operative measures there were of melancholia, two, mania, five, puerperal insanity (mania) one, dementia (including four epilepsy), seven (three deaths), paranoia, two, hysterical insanity, two, adolescent insanity, one Total, twenty

The number of my cases is too small to allow one to draw any conclusions, but if anything of practical value can be deduced from them it is that puerperal insanity, melancholia and simple mania offer the best chances of cure from the proper treatment of local lesions in the pelvis Of course it may be said that these forms of mental disorder are just those which yield in the majority of cases to the usual methods of management of insanity In seven of the cases, however, the insanity had lasted over eighteen months before any treatment directed to the local lesion had been instituted In a case of hystero-epilepsy, the patient had been in the hospital seven years, and one of the cases of puerperal insanity had been four and a half years insane I am convinced that earlier operation in appropriate cases would very largely increase the proportion of recoveries

I do not claim that these results prove that insanity is caused by pelvic disease, but they do show that judicious treatment directed to the physical disease benefits the patient's mental condition If that is an object to be desired, then I ask for these results, and for the views I have ventured to express, unprejudiced consideration

SOCIETY PROCEEDINGS.

Chicago Pathological Society

Regular Meeting, June 10, 1895

Weller Van Hook, M D , President, in the chair

(Concluded from p 586)

Dr E R Le Count, read a paper on

EMBOLIC ABSCESSES IN THE KIDNEY DUE TO THE MICROCOCCUS LANCEOLATUS OF FRAENKEL

The following case is submitted on account of the scarcity of similar recorded observations, and as affording positive knowledge concerning the etiology of chronic diffuse nephritis

Clinical History—(Abstract) S C , cabinet-maker, age 35, white, entered the Cook County Hospital Jan 26, 1895 He had been sick one week and complained of pain in the chest Examination revealed increased fremitus over the right lobe, bronchophony, an abundance of crepitant râles, and dullness on percussion The heart showed no enlargement, the sounds were obscured by the respiratory murmur, and there were no adventitious sounds On admission the temperature was 100 degrees F, pulse 118 and respiration 28 On the second day, temperature was lower On the third day at midnight the temperature rose to 104 2 degrees F From this time the temperature remained constantly above 101 degrees F, being frequently 103, 102 8, 104 2 degrees, etc Death occurred February 2, seven days after entrance

Post-mortem (Abstract) The pericardium was smooth and shiny and the cavity empty Heart, weight, 310 gr , size, left ventricle, 7 5 c m long, wall, 1 5 c m thick, right ventricle 8 5 c m long, wall, .3 to 4 m m thick On the anterior surface of the anterior mitral cusp was a large atheromatous area Some similar smaller areas were present on the intima of the aorta in the sinuses of Valsalva The myocardium was uniform in consistence and color Aortic, tricuspid, and pulmonary valves appeared normal Liver, weight, 2,200 gr It measured 21 x 19 x 18 x 8 5 x 5 c m It was rough and granular externally On section, the lobules appeared elevated and the interlobular regions depressed Left lung floated, crepitation was present throughout In the posterior portions there was an excess of blood and the pleura were adherent at the apex Right lung was solid, and maintained its shape when laid on a flat surface When placed in water, the whole lung sank beneath the surface The visceral pleura was thickened and covered with a fibrinous, quite adherent, yellowish gray exudate On section the entire lung appeared gray with a granular surface, from which casts of the more minute air passages could easily be scraped Spleen, weight, 380 gr , size 14 x 10 x 6 5 c m The capsule was wrinkled, there was no excess of connective tissue on section, and the substance of the spleen was soft and almost confluent Right kidney weight, 180 gr , size 12 5 x 7 5 x 4 c m Externally, there were seen a number of depressed areas along the external border, which showed reddish centers On section the cortical and medullary markings were quite distinct The depressed areas noted externally were found to be due to isolated areas of cortical atrophy In the pyramids were found numerous, white, gelatinous-like streaks, extending at right angles to the bases of the pyramid These streaks had the appearance of pieces of silk thread imbedded in the kidney tissue They were never found reaching from base to apex of the pyramid, but always a portion of the distance only, and were generally in that part of the pyramid nearest the pelvis of the kidney In the cortex a few similar areas were found, but in place of being linear they were dot-like The whitish streaks noted in the pyramids measured 1 to 2 mm wide Left kidney was similar to the right in size and weight, and like lesions were found on section The capsule was more adherent than that of the right kidney The other viscera showed no gross changes

Bacteriologic examination (by Dr G H Weaver) cover slip preparations from the pyramidal emboli stained according to Gram's method showed many lanceolate micrococci, arranged in pairs which were single or in short strings By treating with glacial acetic acid, and staining with solution of gentian violet, capsules are seen about the pairs Cultures made on Guarnieri's medium made from the embolic areas gave a growth of cocci which corresponded in every way to the micrococcus lanceolatus

Histologic examination of sections stained with hematoxylin and eosin revealed in the pyramids many linear abscesses or areas of necrosis Where the changes were least marked, the blood vessel (a branch of one of the pyramidal arteriole pencils) was found plugged with leucocytes Around this a small zone of infiltration with polynuclear leucocytes Many of these showed beginning nuclear fragmentation The larger areas were simply exaggerations of the more minute In these (the larger), the connection with the blood vessel was not as easily made out, the zone of leucocytic infiltration was wider, the central necrosis and nuclear fragmentation more marked Sections stained in picrocarmine for twenty-four hours and then by Gram's method gave a beautiful picture of the tissue changes, and showed the centers of the involved areas to contain large numbers of lance shaped micrococci, in pairs and occasionally two or three pairs together forming short strings Capsules about the diplococci were demonstrated in sections

The micrococcus lanceolatus or pneumococcus of Fraenkel was first found in the blood of animals which had been injected with sputum from patients suffering from pneumonia by Klein [1] The subject was afterward studied by Sternberg in this country

Foa and Rattone[2] injected pure cultures of the micrococcus lanceolatus into the kidneys of animals and found localized areas of inflammation as a result Dreschfeld[3] mentions finding the Fraenkel micrococcus in the vessels of the kidney but says nothing concerning the condition of the kidney tissues Senger[4] describes five cases of meningitis occurring with pneumonia, two cases of endocarditis, and two cases of nephritis But his methods were such, that they can not escape criticism as to proof of direct etiologic connection with the Fraenkel micrococcus as was later pointed out by Weichselbaum The last named author[5] in 1886 found the micrococcus lanceolatus in the connective tissues of the mediastinum, between the esophagus and vertebræ, and about the trachea, in cases of pneumonia Mircoli[6] described one case of primary acute nephritis in which he found encapsulated micrococci which stained with Gram's method These he considered as identical with the pneumococcus of Klebs Weichselbaum [7] again in an article on some of the rarer localizations of the micrococcus lanceolatus described one case of ulcerative endocarditis which followed pneumonia in which this microbe was found by culture methods in the vegetations of the aortic valve, and in an embolus of the Sylvian artery and the surrounding localized meningitis In this case two infarcts were found in the spleen but nothing was said concerning their bacteriologic nature or the histologic changes in the spleen tissue In another case of endometritis, peritonitis and pleuritis, the Fraenkel micrococcus was found as an etiologic factor in all places and it was recovered by culture methods from the kidneys The liver and kidneys presented a cloudy appearance and seemed swollen In sections from the kidneys a few micrococci were found in the small blood vessels

A third case of this series was a case of pneumonia complicated with suppurative joint inflammation At the autopsy a large infarct was found in the spleen, and in the kidneys were smaller infarcts Cultures from the kidneys were negative In sections from the kidney and spleen infarcts only few micrococci were found, and these in the small blood vessels The author believed these processes to be due to the Fraenkel micrococcus and accounted for the paucity of bacteria by the fact that being dead they would not take the stain As is well known this microbe may cause suppurative inflammation

Illustrative of this, Zaufal [8] in an article on otitis media notes its occurrence in an abscess in the region of the mastoid Weichselbaum [9] finds it as the direct cause of a case of primary acute peritonitis and Boulloche [10] describes in detail a case of multiple suppurative arthritis and myositis caused by the micrococcus lanceolatus Ortmann and Samter [11] were among the first to describe abscesses of the soft parts due to the micrococcus of Fraenkel The case was not unlike puerperal pyemia, but occurred in the male Abcesses formed in the right thigh, right and left popliteal regions, lumbar and coccygeal regions The observers also made mention of infarcts the size of a pea in the kidneys of a rabbit which was inoculated with a culture of the micrococcus lanceolatus, and in the infarcts the same organism was found

Nauwerck[12] found in two cases of nephritis which occurred as complications of pneumonia, cocci in the glomerular capillaries which he considered as identical with Friedländer's pneumococcus His results were incomplete as he made no cultures, nor was Gram's staining method employed

Pansini[3] reported four cases of primary acute nephritis due directly to the Fraenkel micrococcus He suggested that the microbe might emigrate upward, as it has been found often in the normal urethra

A case of primary importance is that reported by Eisenlohr [14] The patient had pneumonia in December, 1890, at which time the following symptoms of an acute nephritis developed anasarca, pleural effusion, urine, 6 per cent albumin, casts, red and white blood corpuscles, sp gr 1020 to 1015, quantity twenty-four hours, 1,000 to 1,400 c c m Recovering from the pneumonia, she suffered from uremic symptoms in January, 1891, at which time the quantity of urine dropped from 1,000 or 1,500 to 300 c c m for every twenty-four hours During the following summer the urine contained 2 to 3 per cent albumin Oct 14, 1891, symptoms of uremia again developed, which resulted in death four days later At the autopsy the kidneys were found small and granular , right, 9 x 6 4 c m , left, 9 5 x 5.3 c m The cortex measured 2 to 3 m m only The glomeruli appeared as small pale-red points, and the capsules were adherent Microscopic examination revealed in the cortex numerous large and small areas of round cell infiltration between the glomeruli and convoluted tubules, numerous hyalin casts in the tubules desquamation of the tubule lining, and in the pyramids also, round cell areas

While there was no way of proving in the case just cited, that the condition of the kidneys, and consequent uremia, was due to the localization in the kidneys of the micrococcus lanceolatus, the data here somewhat cursorily brought together seem to warrant the following conclusions

That an infection of the blood with the micrococcus lanceolatus may occur as a complication of pneumonia

That the secondary localization of these may cause various lesions, abscesses, septic infarcts, simple areas of necrosis, etc

That an acute nephritis during or following pneumonia, may be caused by embolic processes due directly to the micrococcus lanceolatus

That in the event of recovery from the pneumonia and the acute nephritis due to such embolic lesions, the resulting kidney lesions may play *an important part in the* production of a chronic diffuse nephritis

DISCUSSION

DR JAMES B HERRICK—The more we learn concerning the pneumococcus the more, it seems to me, do we see that we do not thoroughly understand this microörganism and the pathologic changes and clinical manifestations that it produces Clinically, at least, it seems not improbable that under the head of pneumococcus may be included diplococci that, though morphologically alike, are in reality not identical The pneumococcus shows itself in the lungs in the manifestation of croupous pneumonia It may excite inflammations of the various serous membranes, those covering the heart, its lining, *membranes of the* joints and not infrequently the meninges We know, *too* that in some unknown way it seems to excite epidemic cerebrospinal meningitis, and encephalitis I have seen an autopsy of a case where the sole finding was a little softened inflammatory area in the encephalon that contained nothing but a pure culture of the pneumococcus No infection atrium could be found in that patient after a most careful search

The findings of Dr Le Count seems to warrant his statement that in some cases of pneumonia the blood itself becomes infected with the pneumococcus

I have read an abstract of an article by some Italian whose name I can not at present recall, in which he claims to have found the pneumococcus in the blood of twenty-five consecutive patients with pneumonia In about half the cases the examination was made post-mortem, and in the remaining half the examinations were made during life Just how reliable his methods are, one can not accurately judge from the abstract His method of examination was to withdraw blood from the patient's blood vessels and inject a rabbit The rabbit died of pneumococcal septicemia He concluded as the result of his examinations that in cases of croupous pneumonia the blood was always infected

The practical bearing of Dr Le Count's paper is that the kidney should always be carefully examined, through the urine, as an aid in prognosis, and as an assistance in explaining the protracted course of cases of pneumonia such as the one just described

DR FRANK X WALLS—I have never seen a case of pneumonia with this complication, consequently *I have but little* to add to what Drs Le Count and Herrick have said A question of interest is a possible *explanation* of why this disease is so infrequent Suppurative *complications* in other organs of the body during the process of pneumonia are not infrequent, more particularly of the pleura, the peri- and endocardium, the meninges, etc Multiple renal abscesses in the course of other diseases, especially of a pyemic character, are frequent, and their frequency is explicable when we consider the histology of the kidney Yet, despite the frequent occurrence of suppurative processes in pneumonia, this kidney complication is exceedingly rare It is well known that the diplococcus exhibits great variation in the virulence *of its toxic* properties, as has been shown by experiments on animals It is the property of the kidney to eliminate toxins, and thus may render the bacteria inert, and explain why the *complication* is so infrequent That the kidney does eliminate *these toxins* in considerable quantity, abundant clinical and post-*mortem evidences* of renal damage during the course of pneumonia, *would seem* to bear witness The diplococcus has been *found in* the *urine* of pneumonia patients

A case of pneumonia which Dr Herrick recently saw in consultation, an elderly man, who died on the eighth day, I saw shortly before his death His urine, when examined showed, in addition to considerable albumin and blood, a considerable number of *cocci* But this was a case of nephritis which occurred at about the crisis of pneumonia Probably *the* infrequency of these lesions is due to the fact that ordinarily the diplococcus is mild, and the renal epithelium is able to take care of what toxins may be produced, until under unusual conditions of virulency these germs paralyze the integrity *of the* renal epithelium and abscesses form The Doctor has suggested that sometimes the disease is produced by secondary extension from the pelvis It might have been in this case secondary to a pyelitis, which is a much more frequent *accompaniment* of pneumonia than are multiple renal abscess

DR LE COUNT (in closing)—*In answer to Dr* Walls, I wish to state that there was no pyelitis and the kidney changes, both gross and microscopical, were not such as could be *explained by an* extension into the kidney substance from the pelvis of a pyelitis In the cases Pansini reported he merely offered that supposition as a possible explanation

---

American Public Health Association

Proceedings of the Twenty-Third Annual Meeting held in Denver, Colo, Oct 1–4, 1895

FIRST DAY—TUESDAY—OCTOBER 1

The Association was called to order at 10 30 *o'clock* A M by the President DR WM BAILEY of Louisville, Ky, in the Brown Palace Hotel, with sixty-five *members, delegates* and ladies in attendance

The President in a humorous vein congratulated the Association, because *the members* had had the opportunity and privilege *of meeting in* the beautiful city of Denver

DR HENRY SEWALL, chairman of the Local *Committee of* Arrangements, delivered the Address of Welcome to the visitors, and explained the symbolic features of the badge which was to be worn by them for the purpose of indentification The violet ribbon typified the State flower, the columbine, while the yellow or gold colored ribbon to which it was joined was an exhibition of courtesy and intended as a compliment to the Eastern members who were *generally* regarded as "gold bugs," others thought the yellow ribbon indicative of the sun flower The silver brick and pin with which they were fastened, having on one of its three sides the letters Denver, A P H A, and 1895, needed no explanation, and as the suggestion had also come *from* the East that the bottom had dropped out of silver, *the analogy had* been *carried* out by making the brick hollow, *another compliment to the Eastern members* which they would doubtless appreciate *Your duties are largely regarded as those* of a *missionary* sense, and we expect to profit as a *result* of the good cause you are engaged in, and we gladly welcome you to the Centennial State The chairman then made a number of announcements appertaining to the various social entertainments for the visiting delegates and their families

REPORT OF THE EXECUTIVE COMMITTEE

This committee, by Secretary Watson, *submitted* a *list of about seventy applications* for membership which the committee *had considered* and *recommended* that they be elected members of the Association *Upon motion* to that effect, the secretary was authorized to cast the unanimous ballot for the names presented He also read a telegram, dated at *Chihuahua, Mexico, from the* Mexican delegates, stating that they were delayed on account of a washout along the railroad

The first paper announced,

THE MISSISSIPPI RIVER AS A SEWER,

and was read by DR JOSIAH HARTZELL, of Canton, Ohio, member of the Ohio State Board of Health The author produced statistics to show the tremendous quantities of dead animal matter which yearly floated down the Mississippi, and the consequent damage to public health *He* criticised Chicago and the sewer purposes to which it devoted the Chicago River Comparisons were made of the Valley of the Mississippi, with the Nile, Rhine and Chinese rivers, and gave an estimate of the territory drained and the consequent amount of filth, dead and decaying vegetation, carcasses of animals, etc , that were washed into the river, converting it into a *cloaca maxima* for the whole interior basin of the continent In Leeds, England, the authorities, on complaint of the residents living below the city, prohibited the municipal government from using the stream for such purposes, and that must be the ultimate result in this country Strict National legislation to prevent the principal streams of the country from pollution, in order to save the game fish in those streams was suggested Whether this result will be obtained, he doubted, so long as the average politician is engaged in scrambling for office, as he is not a *sanitarian and is not* greatly interested in public health matters *Incidentally, the* writer gave a brief description of the great drainage *canal at Chicago*, and the benefits to be derived therefrom *Disposal of* sewage in the cities of Berlin, Paris, London and New York were *mentioned* and briefly described The fever plagued cities of western Pennsylvania, West Virginia, Ohio Illinois, Minnesota and Nebraska were also mentioned The statutes of Illinois, Ohio and other States were quoted at length, regarding the pollution of streams The laws on fish culture were also quoted *in extenso*

The remedy advocated, is the establishment of a government commission, analogous to the English Rivers Pollution Commission, or the German Imperial Board of Health This commission should supervise the sanitary condition of navigable waters, and should have ample authority So long as the general government is inert and indifferent in regard to this matter, the State Boards of Health of all the States bordering on the Mississippi system of waters are handicapped Their efforts to suppress epidemics arising in other States and carried to them through the medium of rivers under government control, are paralyzed No general plan of sanitation and of stream purification can be successful until the State Boards of Health have the practical coöperation of the Federal authorities and this can be accomplished by a National Department of Health or a commission appointed by Congress having this matter under its charge

The succeeding paper was upon an analogous topic,

WATER POLLUTION, AND PURIFICATION OF WATER SUPPLIES,

read by Dr Peter H Bryce, of Toronto, Secretary of the Provincial Board of Health of Ontario, who considered the subject mainly in its international aspect He criticised the authorities at Buffalo and the recklessness with which they distributed garbage, so that contractors *might* be the gainers, commercially, in relieving that city of its unpleasant effects, while the cities across the border would be *the sufferers* He cited instances in which he had pursued some garbage boats in a cutter in Lake Ontario, *and stated that* the government had narrowly escaped an international complication on account of *what he had done It was the duty* of health officers on both sides of the line to see that sanitary regulations were rigidly enforced Especially was this true, regarding the St Clair or Detroit River, and the Niagara River

DISCUSSION

Dr Ernest Wende of Buffalo, N Y, desired to make a correction regarding the disposal of garbage in his city Buffalo cremates her garbage, and does not deposit it in the Niagara River or Lake Ontario

Dr A W Cantwell, of Davenport, Iowa, said regarding the pollution of the waters of the Mississippi River, that he thinks their purification can only be brought about by National legislation, and the same authority will prevent the dumping of garbage into our rivers The proper method to dispose of the latter is by cremation, and this costs something

Dr E A. Guilbert, of Dubuque, Iowa, said he deeply appreciated any action that may be taken in this matter by this Association and that this matter was before the last Congress His State Board of Health commended the bill, as this can not be done by State legislation

Dr P H Bailhache, of Staten Island, N Y, said that if this matter, or any bill having for its object the passage of such measure was before the last Congress, that the subject was dead—as the last Congress had died

Dr J J Kinyoun, of Washington, D C, thinks the subject of the pollution of water supplies in the United States is unique and stands alone He advocated the appointment of a special commission to take charge of this matter

Dr. Felix Formento, of New Orleans, La —We should not lose sight of local interests from a sanitary point of view These platonic recommendations are not usually acted upon We should do something beyond the expression of our opinions We must have a practical plan I do not think the lower Mississippi is polluted, as has been stated, from the offal deposited in its waters several hundreds of miles above New Orleans

Dr J N McCormack, of Bowling Green, Ky, moved, duly seconded, that a committee of three, members of this Association, be appointed by the chair, with Dr Bryce as chairman, having full power to formulate a plan and suggest to Congress that something in the way of National legislation in this matter should be done

Dr R H Lewis of Raleigh, N C, thought that this committee should suggest to Congress just what should be done, and that it should submit the plan to be carried out

The motion then prevailed

Dr E P Cook, of Mendota, Ill thought that there is no subject more worthy of our consideration than that of water pollution and pure water supply Purity of water for domestic purposes and drinking purposes is one of the great problems that we are now discussing in interior Illinois where I live Filtering and sterilization will do it, but a cheap method is what we are desirous of getting What disposition is to be made of garbage, rubbish and sewage is another very important subject to deal with Cremation of the former is costly where a crematory would have to be erected and kept in operation in a small city of 5,000 inhabitants, while the latter, we know, when it finds its way into our wells and small streams contaminates the water in them This is inevitable Regarding Chicago and her disposal of sewage, the nearest course to the sea is through its new drainage canal, the Illinois and Mississippi Rivers He thinks our Canadian neighbors should be under obligations to Chicago for diverting her sewage away from the lakes

Mr R Hering of New York, spoke from the standpoint of a civil engineer He heartily indorsed the sentiments set forth in both papers, in their ideas of the purity of water supplies He believed in National legislation upon this subject, although some of the questions advanced in the first paper are impracticable People can not pay for complete purification of drinking water The question is not nearly as serious as has been made to appear here to day An estimate has been made that we can not precipitate the sewage for less than 30 cents for every man, woman and child Regarding the Chicago drainage canal, 600,000 cubic feet of water per minute from Lake Michigan, passing through it, will purify the stream along down the canal and river to the Mississippi, then the Chicago River will not be nearly so bad as it is now All waters for drinking purposes should be filtered by those residing in large cities As for garbage, this should never be permitted to be put into streams Civil engineers are often confronted with these questions, and almost as frequently perhaps, it is a question of not what we ought to do, but what we are obliged to do, as the next best thing on account of lack of money

Dr C O Probst, of Columbus, Ohio, said that the farmers in Ohio have combined together and given bonds, and in two or three instances they compelled cities for *instance Canton,* Oberlin, and Fostoria, to purify the water supply or erect a crematory as was done in the latter city These cities at first refused to do this Fostoria built what they call an *intermitting chemical plant*

Dr Bryce closed the discussion, by stating that he thought a civil engineer like Mr Hering should be made a member *of the committee*

The concluding paper of the first session, was "The Report of the Committee on Animal Diseases and Animal Foods," by D E Salmon, D V M, chairman, Washington, D C, which was read by Dr Hewitt of Minneapolis The report was brief and one of the material points it contained was that the United States government should have control of *meat inspection*, particularly is the inspection of pork carried on in a perfunctory manner, and it is not thorough *in the various States in the Union*

The report was discussed first by Dr P H Bailhache who stated *that the inter-state law* is drawn as closely as it can be, for the enforcement of any law, and the Federal government can not further interfere It has no right to step in and order anything done different from that which has been properly enforced by any State

Dr Carl Weidner of Louisville, Ky, said he could not in*dorse the argument of Dr* Salmon in the matter of pork inspection as being inadequate and useless for trichina This *argument is dangerous* A thorough microscopic inspection will detect trichinous meat We might as well say that we can not detect polluted water This argument is unjust to the people Thorough inspection will do a great deal of *good*

Dr Hewitt stated that he does not take kindly to State *inspection Tuberculin* and mallein is supplied to a State when requested, from the United States *government Over* one thousand animals in Minnesota had undergone the test Coöperation between a State and the nation is easily arranged, and this is a practical way to accomplish that which is desired

Dr Kinyoun *indorsed* in the main the views contained in the report, but thought not enough emphasis was placed on the matter of tuberculous meat While the greater portion of bad meat can be detected if the carcasses are carefully *inspected* yet as long as we shut our eyes to microscopic examination, we are going to invite tuberculosis

Dr H N Avery *of* Indianapolis, Ind —In relation to tuberculous meat and swine fever, nothing but local inspection by local health officers can detect these conditions This should be done by meat inspectors At Indianapolis nearly five hundred head of milch cows had been inspected in the last thirty days The sputa, and milk, cheese and butter should all be examined microscopically Ocular and physical examination are entirely useless Tuberculin is the only infallible test, and in nine cases out of ten, we can detect tubercular disease if it is present

Dr Henry Mitchell, of Ashbury Park, N J, Secretary of the State Board of Health of New Jersey, offered the subjoined preamble and resolution, which under the rules was referred to the Executive Committee

Whereas, An order of the Post Master-General prohibits the use of the mails for the transportation of diseased tissues

Whereas, Specimens suitable for bacteriologic examination can, when inclosed in proper packages be transported in the mails without endangering the health of persons who may handle them, and without risk of contaminating other mail matter

Whereas, bacteriologic examination in cases of tuberculosis and certain other infectious diseases constitute an invaluable defense against the spread of the pestilential affections by providing an exact method for early and accurate diagnosis Therefore be it

Resolved, That the American Public Health Association hereby respectfully requests the Postmaster-General to so modify the order now in force that specimens of diseased tissues, when properly inclosed in approved mailing packages, may be admitted to the mails for transmission to State and municipal laboratories

First Day—Afternoon Session

The afternoon session was called to order at 2 45 o'clock with President Bailey in the chair, and was devoted to a symposium on Car Sanitation The first paper presented on this subject was a brief one, and in absence of its author, Mr E C Jordan, C E, of Portland, Me, was read by Dr A G Young, of Augusta, Secretary of the Maine State Board of Health Although the writer made no recommendations, he described the manner in which the Pullman and Wagner sleeping car companies cleaned their cars, removing rugs, carpets, mattresses, etc The mattresses are renovated every six months and the blankets changed once in three months In case of any infectious disease the utmost care is used, and disinfectants are liberally applied

The second paper was

ON THE VENTILATION OF RAILWAY COACHES,

by Prof S H Woodbridge, of Boston, Mass, (one of the professors in the Institute of Technology of that city) which was, in the absence of the author, read by Dr S H Durgin, ex-President of the Association The following is a brief synopsis

In enumerating the discouragements which meet those trying to secure perfect ventilation, the author stated that human frailties were a greater obstacle than mechanical difficulties The ventilation necessary in a hospital is unnecessary in a railway coach, and accommodation trains require less ventilation than cars used on lightning express trains The per capita space is about sixty feet in the average day coach To regularly supply the quantity of fresh air requires many improvements on the present unreliable and inadequate methods The use of vestibule cars, made up for long runs, interferes with ventilation from the ends of the cars

These propositions were laid down for the proper ventilation of cars The air must be furnished by other than natural means The supply must be affected as little as possible by the movement of the coach The heat must be furnished from the floor, and the air must be filtered to avoid dust and cinders In winter the air must also be warmed continuously, and regularly supplied without annoying drafts The action must be plenum rather than vacuum, and care must be used to secure perfect distribution An electric fan with a suitable filter was recommended and overhead channels for supplying air The development of electric appliances will assist in securing a perfect system of ventilation Finally, it should be remembered that in all ventilating undertakings but one-half of the requirements are fulfilled when the most perfect apparatus conceivable is furnished The excellence of a tool does not insure the quality of its product Quite as much depends upon the user as the tool, and not infrequently a superior apparatus is made, on its reputation, to bear the burden of the operator's infirmities It would seem to be of more than doubtful utility to equip coaches with carefully designed means for ventilation unless railroad employes are systematically trained to their use, and they and the traveling public are educated to habits of cleanliness and are free from the trouble-making notions and imaginings which prevail, even among cultivated people, with reference to ventilation The proper function of ventilation begins only after cleanliness has done its most perfect work For a long time to come, to an innocent and dutiful ventilation is likely to be laid the sin of uncleanliness of person and environment

Ventilation deals with unseen air, unseen aerial movements, and generally with unseen motive forces The field is rich for a rank growth of notions and imaginings and quackery Hence the large and important part imagination plays in ventilation effects It is important, therefore, that any system planned to give the surest and highest satisfaction should furnish ocular evidence of its existence and of its action In a well ventilated room a raised window through which no air moved inward has often been known to give great and immediate relief Any successful crack ventilation must include such self announcing means as shall enlist imagination in its favor and put an effective stop to window raising, that fatal disturber of the working of artificial ventilation In conclusion, he thought the imagination was an important factor and not to be overlooked in any system of ventilation, but the railway managers should be required to remove every reasonable excuse for opening car windows

The next paper announced on the program,

RELATING TO CAR SANITATION,

was by Dr Domingo Orvananos, of Mexico, Mex, and was presented by Dr C O Probst He briefly described the opposite ideas which prevailed in the United States and Mexico with reference to car ventilation, due to the different climatic conditions The subject was one full of difficulties In Mexico, where the railways are generally traversing high ground, the ordinary way of opening a few windows keeps the car comfortable, while he had noticed that in America the travelers generally wished the ventilators removed and the windows closed, the reverse was the case in Mexico The ventilation must be regulated according to the temperature It is much more difficult to devise a means of ventilating sleepers than day coaches He finds the prevention of the transmission of disease an even more difficult matter than the regulation of ventilation, but thinks the Mexican railways are better off than those of the United States

1 The cars, except the sleepers, are not furnished with upholstered seats

2 Only a limited number of persons travel

3 Two of the commonest infectious diseases, tuberculosis and diphtheria, are almost unknown in Mexico Other infectious diseases are not propagated in railway cars because convalescents are not allowed to travel After much investigation, he had only found a few cases of bronchitis, pneumonia and pleurisy which originated in cars In treating of measures on this subject, it is always necessary to insist on them until their adoption is obtained The measures he advocated were

1 Watchfulness on the part of the local sanitary authorities to whom pertain each of the railroad stations with large traffic, and with the object of preventing the embarkation of individuals who might transmit the diseases

2 The appointment of medical inspectors on the lines or in the places where it is considered necessary

3 That the railroad cars should be furnished with cushions and hangings that can be easily taken off and replaced

4 The disinfection of the cars themselves, either wholly or in part, whenever the medical inspectors should deem it advisable

5 The prohibition under severe penalties of expectorating in any part except in the cuspidors, of which a sufficient number should be provided, and which should contain a solution of bichlorid of mercury of 1 to 1,000

The last paper on the program and the most thorough treatment of the subject was the

REPORT OF THE COMMITTEE ON CAR SANITATION,

which was presented by Dr Granville P Conn, of Concord, N H, chairman of the committee He invited attention to the fact that his subject was one which was evidently growing in interest, the proof of this being amply shown in the fact that there were three papers on this question, and a whole session devoted to its consideration Dr Conn thinks there is danger of overlooking the ventilation of the day coaches, in dwelling on that of sleeping cars He spoke also of the necessity of holding employes responsible for the condition of the cars in their charge, and cited the Wagner Palace Car Company as having instituted a school of instruction for their train employes A number of reports from various railways were submitted, showing the sanitary precautions used in the care of cars, supply of drinking water, ice, etc A fact cited worthy of note was the international conference on sanitary care of railways which was recently held in Amsterdam Its object was to consider the methods in use in various countries to care for the interest of travelers on land and sea Its work was divided into three heads 1, capacity of officials, 2, medical service, 3, hygienic interests of travelers and employes As yet the sessions have not been made generally public

For the purpose of obtaining accurate information, Dr Conn sent out a circular letter to the general passenger agents, and was generally referred to the managers of the rolling stock The answers show a wide range of opinion and practice in these matters One road having one of its termini in Denver says it has *no sanitary system*, and does not believe it would be practicable or necessary to have an inspection similar to that made of the wheels The Chesapeake & Ohio railway has a very satisfactory system, as has also the Baltimore & Ohio The conditions on the Southern Pacific are by no means reassuring to the traveler Dr Conn said, in conclusion, that this was a matter which was receiving more and more attention, and that the through line that takes the most advanced position in alleviating the discomforts of the traveler, that shows by the cleanliness of its cars, their heating and ventilation, and above all by the uniform *courtesy of their employes*, the fact that they have a department of hygiene as well as of surgery, will reap its own reward, and save thousands of dollars in its advertising department Of the preceding papers, he said the conservative manner in which Senor Dr Domingo Orvananos, of the Republic of Mexico, has treated the subject of car sanitation, I most heartily commend the same to the public, and to the railway managers of countries now embraced by this Pan American Association The sentiments contained in his report are those of wisdom and ripe judgment, and are worthy of the man, as well as an honor to the Republic of which he is a representative sanitarian

The report of Professor Woodbridge, of Boston, is a clear and concise statement of the sanitary conditions which he found in railway cars that came under his observation, and the suggestions which he has made are to be noted, and if adopted by railway companies would insure to the public more healthy conditions in traveling, and prove of immense value to the railroads themselves

DISCUSSION

Dr Kinyoun called renewed attention to the disinfection of coaches, especially of the sleeping cars of any of the sleeping car companies They should be disinfected at the end of the route, or of every trip if it lasts over twelve *hours Phthisis* diphtheria and perhaps pneumonia and the exanthems could be transmitted from State to State, hence the most stringent methods should be insisted upon everywhere What germicide shall we use for the germs of tuberculosis? A 15 per cent volume of burning sulphur is not sufficient, although it might do for the exanthems *Steam will, in a certain* sense, prove adequate when used by an experienced or competent person An ordinary car can be disinfected in ten minutes by the use of a spray of formalin which he had found to be the best disinfectant or agent to kill smallpox and other germs It is more effective than tricresol or carbolic acid and is easy to handle

Dr Durgin inquired of Dr Kinyoun if he had considered the separation of the upholstered work, mattresses, etc, from the woodwork in the use of formalin or sulphur

Dr Conn closed the discussion by saying that formalin is a well known agent, and when it dries, it forms a dust or powder that will kill germs in the carpets and in the other furnishings of our cars He also stated that he thinks the mechanic and the sanitarian are coöperating in this matter

At 4 10 o'clock the session adjourned until 8 P M

First Day—Evening Session

The Association re assembled at 8 15 o'clock P M at the Trinity M E Church with the President and Vice-President (alternating) in the Chair Others on the platform were ex-Presidents La Chapelle, Montizambert, Hewitt, Formento Durgin, His Honor Mayor McMurray, His Excellency Governor McIntyre and Chancellor McDowell Several organ solos were rendered by Dr J H Gower After prayer, President Bailey introduced Governor McIntyre, who formally welcomed the Association to the Centennial State as follows No Association which had honored Denver with its presence was more important in the subject matter of its deliberations than the one which had just convened He drew a comparison between the treatment of the health of the individual as contrasted with the health of individuals in the aggregate So important is this subject that even now the matter of public health does not receive the consideration which is its due He believed in the elevation of the public health officers to the position of recognized State officials He heartily welcomed the Association to this State and capital, and closed amidst applause

Mayor McMurray was then introduced He said it was a pleasing duty which devolved upon him to welcome them individually and as an Association The subject to which they devoted themselves transcended in value any that could come up for consideration among any body of men or women, for the human life is of preëminent importance Whatever the line they might consider, whether disease in the epidemic or ordinary form, their effort was to advance the public welfare Whatever they did he hoped they would have a very pleasant and profitable time while in Denver and that the result of their labors would be of value not only here but in every community from which they hailed He hoped their stay would be enjoyed and they would find pleasure in returning here in the days to come in their capacity as private citizens The Mayor was greeted with a burst of hearty applause

The magnificent "Offertoire" of Batiste was then rendered by Dr Gower, after which Dr Wm Bailey of Louisville, Ky, was introduced to deliver his Annual Address as President of the Association Dr Bailey begged to acknowledge the honor of having been President for the past year The Association numbered in its members and workers some of the most illustrious sanitarians of the continent "I congratulate the Association," said Dr Bailey, "upon its meeting in the convention city, the Queen City of the Plains, the beautiful city of Denver In the wonderful State of Colorado, fit Centennial State, with advantages as yet untold, with a climate that will challenge the admiration of the sanitarians as perhaps none other can, with an atmosphere of marvelous purity almost sterile as to pathogenic germs, and without the necessity of international agreement of unlimited coinage, the coin of the realm, the parity of which is guaranteed and maintained by the Almighty himself

"The American Public Health Association had a valuable object lesson of the good the Association had done by a reduction of 50 per cent in the death rate of this city," Dr Bailey continued "The past year had been a good one from a health standpoint Cholera threatened the Western border, but the efficient corps in California might be depended upon to keep it out, calling for assistance if need be He spoke of the importance of quarantine regulation, and the value of the report on the purity of water supply A number of college professors were unable to attend the meeting because of the college sessions having commenced This suggested the change to an earlier date the time of meeting The Association should perfect its plans to celebrate the centennial anniversary of Jenner, the discoverer of vaccination He suggested a memorial report He said there was hope that in time they would be able to afford immunity from such diseases as cholera, scarlet fever, diphtheria and consumption, as they now have immunity from smallpox"

The speaker wondered that there was not a National Department of Health Gladstone had termed the work the highest object of government More careful quarantine laws were needed Careful inspection would prevent many of the contagious and infectious diseases The difference between the government of the United States and foreign governments in respect to the investigation of diseases and their causes was contrasted Professor Koch was assisted by his government

The question of the pollution of the water supply was next touched upon Nothing was of more importance than the purity of water He hoped the members of the convention would assist the work of the committee appointed to investigate this vital question

"The greatest question," said the speaker, "to sanitarists is immunity from disease Management of disease must become more national as this was investigated and made known" He quoted the result of vaccination in lessening the ravages of smallpox in proof of his statement, and added that smallpox should be considered a disgrace to a city He advised a report setting forth the truth regarding vaccination so as to remove false impressions Such a report would be a fitting memorial to Jenner He gave it as his opinion that immunity from other infectious diseases was sure to come in a few years as a result of study of bacteria and disease germs

Chancellor McDowell was the last speaker on the program He said that the public health question had made many persons uncomfortable He was afraid to go anywhere because he feared to meet a microbe with a club It was uncomfortable because the physicians had turned the microbe loose Now there was but one thing to do That was to give public health the right of way He believed in personal liberty, but personal liberty required some restraint because of the public welfare The man who refused to obey the public health officer deserved punishment Were not the water rates so high he would favor the mayor turning the hose on the offender The health office should be taken out of politics If it were kept there he feared it would become full of microbes The speaker urged upon the public the necessity of joining with and seconding the health officer in his work, and closed by a wish for the thorough enjoyment of the delegates during their stay

At 9 30 o'clock the Association adjourned until Wednesday forenoon

(*To be continued*)

BOOK NOTICES

The Pathology and Surgical Treatment of Tumors By N Senn, M D, Ph D, LL D, etc, etc Illustrated by 515 engravings, including full page colored plates 8vo, pp 709 Philadelphia W B Saunders 1895

In the year 1890, Professor Senn in the preface to his work on the "Principles of Surgery," said "When the subject of tumors was reached it was found that the manuscript had become so voluminous that it was deemed advisable to publish the volume without this part of the intended scope of the work, an arrangement to which the publisher kindly gave his consent It is the author's intention to make good this defect by the preparation in the near future, of a special work on "The Pathology and surgical Treatment of Tumors'"

The book under consideration is the outcome of the promise made five years ago, and the promise has been well and faithfully performed in the production of this handsome volume

There are thirty chapters, viz i, Origin and Nature of Tumors, ii, Morphology and Multiplication of Tumor Cells, iii, Anatomy and Biology of Tumors, iv, Pathology of Tumors, v, Tumors in Plants and Animals, vi, Etiology of Tumors, vii, Clinical Aspects of Benign and Malignant Tumors, viii, Transformation of Benign Tumors and Post-Natal Embryonic Tissue in Malignant Tumors, ix, Diagnosis of Tumors, x, Prognosis of Tumors, xi, Treatment of Tumors, xii, Classification of Tumors, xiii, Papilloma and Onychoma, xiv, Adenoma, xv, Cystoma, xvi, Carcinoma, xvii, Fibroma, xviii, Lipoma, xix, Myxoma, xx, Chondroma, xxi, Osteoma, xxii, Odontoma, xxiii, Angioma, xxiv, Lymphangioma, xxv, Lymphoma, xxvi, Myoma, xxvii, Neuroma, xxviii, Sarcoma, xxix, Teratoma, xxx, Retention Cysts

This book is the most exhaustive of any recent book in English on this subject It is well illustrated and will doubtless remain as the principal monograph on the subject in our language for some years It will be observed that the new spelling has been generally followed

The book not only includes the pathology of tumors, but in describing the surgical treatment discusses fully the operative surgery of the regions involved Those interested in any special branch of operative surgery, except ophthalmology, will find the modern operations described in detail The vast experience of the author has told its own story in these pages, which are replete with solid information, and his masterful acquaintance with German literature shows itself at every turn The book is handsomely illustrated, and printed on good paper Many of the illustrations are inserted plates The publisher has done his work well, and the author has given a notable and lasting contribution to surgery

Cutaneous Medicine, A Systematic Treatise on the Diseases of the Skin By Louis A Duhring, M D, etc, etc Part i, Anatomy of the Skin, General Symptomatology, General Etiology, General Pathology, General Diagnosis, General Treatment General Prognosis Illustrated Royal 8vo, pp 221 Philadelphia J B Lippincott Company 1895

"The present work," says the author, "has been written to take the place of the author's former 'Practical Treatise on Diseases of the Skin,' which for several years has been out of print"

The vast experience of Prof Duhring as a teacher and practitioner makes his statements authoritative, and his book trustworthy in all matters pertaining to dermatology proper The author, pp 216 and 217 in mentioning skin grafting, quotes the old Hunter experiment of the transplantation of the cock's spur, and of the tooth, and then passes immediately to Reverdin's epidermal grafts in 1869 The remarkable experiments of the late Frank Hastings Hamilton, then of Buffalo, in skin grafting, set forth in a paper read June 27 1854,[1] more than fifteen years prior to the appearance of Reverdin's paper, which appeared in the *Gazette des Hôpitaux* for Jan 11 and 22, 1870, are not noticed

As a rule, the author has very carefully noted all recent literature and has even quoted from papers read at the last meeting of the Association in 1895

The paper is thin and inferior, but the illustrations are numerous and well executed plates carefully inserted We shall look with interest for the remaining parts of this system The author has great power of condensation There is no superfluity or redundancy in his expressions, always clear, never involved, and withal extremely precise, he manages to put nearly twice as much in a page as the average writer The work therefore, will be encyclopedic without being bulky

A Text-Book on Nervous Diseases By American Authors Edited by Francis X Dercum, A.M, M.D, Ph D With 341 engravings and 7 colored plates Philadelphia Lea Brothers & Company 1895

We have in this volume the latest of "American" text-books, and one that worthily maintains the honor of the American name The list of the authors who have contributed, under the able editorship of Dr Dercum, to produce this work is enough to justify expectations that will not be disappointed on its careful examination As a composite production it perhaps lacks the symmetry that a single authorship would give, but this is so little an advantage that probably most of its readers will prefer it as it is

Among the articles deserving especial mention as most excellent statements of our present knowledge of their subjects, may be mentioned the introductory chapter on Methods of Examination, by Drs Weir Mitchell, Dercum and Oliver, that on Nervous Affections following Railway and Allied Injuries, by Dr Philip Coombs Knapp, which is one of the best and most judicious descriptions of this forensically important class of cases, that we have seen, the chapter on Cerebral Localization, by Dr Mills, which seems thoroughly up to date, and that on the Diseases of the Cranial Nerves, by Dr de Schweinitz We mention these, not invidiously, as better than the rest, but simply because for one reason or another they particularly attracted attention All the contributions to the volume seem to be excellent, and the book is cordially recommended to American readers as representing the actual status of our knowledge of its subjects, and as the latest and most fully up to date of any of its class

Modern Materia Medica, with Therapeutic Notes for the Use of Practitioners and Students of Medicine By Dr Otto Roth Seventh edition Revised by Dr Gregor Schmitt 8vo, pp 467 New York Wm Wood & Company

Whatever may be the uses of this book in Germany, if it is ever to be of any particular service in the United States it must be brought to conform to the United States Pharmacopœia As it has been produced, it is in the first part a mere catalogue of drugs and in the second a list of diseases with reference to the appropriate drug therefor The obsolete dosage of the old British and United States Pharmacopœias is used, which is all the more remarkable, as the United States Pharmacopœia of 1890 adopted the decimal system and the present revisers of the British Pharmacopœia long ago announced their intention of joining the remainder of the civilized world in the use of the decimal system of weights and measures

SATURDAY, OCTOBER 12, 1895

THE TREATMENT OF DIPHTHERIA BY ANTITOXIN

WELCH contributes an important article on the treatment of diphtheria by antitoxic serum (Bulletin of the Johns Hopkins Hospital, July-August, 1895,) and studies carefully the statistics of the results already reported

In a brief historical introduction, he shows that while BABES and LEPP in 1889 were the first to show by the way of experiment that it was possible to vaccinate with fluids and cells of animals which had been rendered refractory to certain diseases, such as rabies, yet the first publication clearly demonstrating the principles of serumtherapy was made by BEHRING and KITASATO in 1890, in which they brought forward proof of the immunizing and curative property of the blood and serum of animals artificially immunized against tetanus, and then BEHRING and WERNICKE demonstrated that the serum of animals artificially immunized against diphtheria has the power to protect and cure susceptible animals inoculated with the diphtheria bacillus or its poison In the fall of 1891 the first trial of serum of immunized animals in the treatment of human diphtheria was made in VON BERGMANN's clinic in Berlin In April, 1893, BEHRING referred to thirty cases treated with so called normal serum In April, 1894, EHRLICH, KOSSEL and WASSERMANN reported 220 cases treated with the serum, and the era of serum treatment of human diphtheria by approximately sufficient doses of the antitoxin really begins with this publication In September, 1894, ROUX presented the subject at the Hygienic Congress in Buda-Pesth with such clearness and force and brought forward so strong and convincing statistics that the attention of the physicians of the world was arrested and the antitoxic treatment of diphtheria has, since that time, *continued to be the foremost medical topic of the day*

While the laboratory does not present any more conclusive experiments than those showing the power of antitoxic serum to prevent and to cure the morbid process caused in animals by the inoculation with the diphtheria bacillus or its poison, yet the question arises as to what extent the conditions of the treatment of experimental diphtheria with antitoxin are similar to those in the use of the same agent in the treatment of human diphtheria WELCH concludes that there is identity in essential points, anatomic and etiologic, between experimental diphtheria and uncomplicated human diphtheria Thus there is no longer any question but that in uncomplicated human diphtheria, as well as in experimental diphtheria, the local inflammation at the site of the infection is caused by the multiplication of the LOFFLER bacillus and that the system's symptoms are due to the absorption .of toxins formed by the bacillus, and, consequently, it would be hard to understand why an agent, such as the antitoxin, which neutralizes the toxins in the animal body should be unable to neutralize the toxic effects of the same substance or substances in human beings At all events WELCH, is firmly of opinion that the results obtained from experiments on animals justify and demand the most thorough and careful trial of this new treatment in human beings

Concerning the nature of the so called antitoxins and their mode of action but little is known There are two prominent theories as to the mode of action of the diphtheric antitoxin, viz , the chemic and the vital The chemic theory holds that the antitoxin directly neutralizes in a chemic sense the toxins Experimental evidence, however, is in favor of the vital theory that the antitoxin acts through the agency of living cells and that it probably renders the cells tolerant of the toxins

Antitoxic serum exerts no bactericidal effect upon the diphtheria bacillus, and virulent bacilli may persist in the throat days and even weeks after recovery, after the use of the antitoxin

The *dosage of the antitoxin* in human diphtheria is empirical The main factors in determining the dose are the age of the patient, the duration and the severity of the attack In this way it can easily happen that an insufficient dose is given and it is now well understood that in the early period after the introduction of serum entirely insufficient doses were used

The most important difference between experimental and human diphtheria is the fact that, while experimental diphtheria is a single, pure infection, human diphtheria is often complicated with mixed infections, the most common complicating microorganism being the streptococcus pyogenes Thus

Reiche found the streptococcus in the kidney and spleen in 45.2 per cent of forty-two autopsies on cases of diphtheria in which Loffler's bacillus had been demonstrated during life; streptococci and staphylococci were found together in 64.3 per cent of these cases; these results indicate significantly the frequency and earliness of the mixed infection. There can be no doubt that the remedial rôle of the antitoxin is materially restricted by its inability to combat streptococcus sepsis, broncho-pneumonia and other forms of secondary infection. It is also a well-known fact that all necrosis and changes in the nerves may occur very early in diphtheria, and it is, of course, evident that the antitoxin can not restore cell life or repair degenerated nerves when such retrogressive changes have occurred before its use. A knowledge of these conditions will emphasize the importance of sufficient dosage and timely administration of the antitoxin.

Having considered the experimental basis and the theories of action of antitoxic treatment, the importance of early use in sufficient doses and some of the pathologic relations of human diphtheria, Welch turns his attention to the evidence at hand concerning the efficacy of the new treatment. He finds that the general impression of clinicians who have had good opportunities to observe the effects of antitoxin is overwhelmingly in its favor and cites the observations of Baginsky, Heubner, Ganghofner and others, who all express favorable general opinions. But general clinical impressions do not furnish any strict scientific proof of the value of a therapeutic agent; here statistics are necessary. Welch has collected 7,166 cases from eighty different sources and it is not necessary to state these have been gathered with all possible accuracy and that they are considered from various points of view, in order to eliminate all the possible sources of error with which statistical results nearly always are vitiated.

Of these 7,166 patients with diphtheria treated with antitoxin, 1,239, or 17.3 per cent died. The previous or simultaneous mortality of cases not treated with antitoxin is stated in forty-six of the reports, which contain 5,406 cases treated with antitoxin, with 1,008 deaths, a fatality of 18.6 cases. Estimating the number of deaths in these cases upon the basis of the previous or simultaneous fatality for each group, there would have been 2,279 deaths, or 42.1 per cent. *There was, therefore, an apparent reduction of case mortality by the use of antitoxin of 55.8 per cent.* Separating the hospital cases from those occurring in private practice, the unusually low death rate of 18.7 per cent is obtained for hospital cases. Welch finds no reason to believe that the low percentage of fatality of diphtheria treated with antitoxin can be referred in any large measure to the prevalence of an unusually mild type of the disease. He does think, however, that a large number of cases are received for treatment in the earlier stages of disease now than formerly, and that for this reason the antitoxin statistics can not always be suitable for comparison with statistics based upon the former treatment of diphtheria, inasmuch as it is universally admitted that any good treatment of this disease gives better results the earlier it is begun. This factor just alluded to is not adequate, however, to explain the great reduction in fatality obtained with the antitoxin.

Roux's analysis of his cases show very clearly that, as would be expected, the serum is far more efficacious in diphtheric anginas and croup which yielded pure cultures of the Loffler bacillus than in those which gave in addition cultures of other pathogenic bacteria. The reports from private practice collected by Welch, give a fatality percentage of only 6.9.

In a second table is shown the fatality in operated and non-operated cases of diphtheria treated with antitoxin. Of the 4,294 cases of this table, 27.2 per cent required tracheotomy or intubation, the fatality in the tracheotomy cases being 39.8 per cent, in the cases of intubation 28.9 per cent, and in the cases of intubation followed by tracheotomy 53.8 per cent. Compared with previous statistics from the same hospitals, this means a reduction in fatality of tracheotomized cases of 34.1 per cent since the introduction of the serum treatment—results that are strikingly favorable to the serum treatment. In the same way it is readily shown that the fatality of intubated cases is reduced 49.5 per cent as the result of the antitoxic treatment. In connection with this, it is to be remembered that the great majority of observers bring testimony of the fact that the stenotic symptoms of laryngo-tracheal diphtheria are relieved without operation in a much larger proportion of the cases treated by antitoxin than by any other method. Von Ranke says that formerly 5 per cent of his stenotic cases escaped operation, whereas now, 33 per cent escape; of Ganghofner's stenotic cases, formerly 12 per cent escaped operation, whereas now, 21 per cent escape.

In his third table, Welch considers the ages of patients treated with antitoxin, and several striking contrasts are presented. Thus the fatality percentage for cases of diphtheria under 2 years of age, treated with serum is 33.3, while it varies 60 to over 80 per cent for cases of the same age not so treated.

Table IV sets forth the fatality according to the day of disease upon which antitoxin is injected. Of 232 cases supposed to have been treated the first day, 5 died; the assumed duration of the disease is, of course, doubtful and in some of the fatal cases in this group the statements of friends and parents were apparently contradicted by the clinical signs and symptoms.

It is very noteworthy that the percentage of deaths in 814 cases, in which treatment was begun before the third day of the disease is only 5 5 According to this table the percentage of deaths in cases in which the serum treatment is begun on the third or fourth days of the disease is nearly three times greater than that in cases treated on the first and second day

The essential harmlessness of the serum has been demonstrated by over a hundred thousand injections, and Welch concludes that should the future show that through some idiosyncrasy on the part of the patient, death might be attributable to the serum, this would probably count for as much as the rare deaths from the use of ether or chloroform The occasional untoward effects of the healing serum, such as erythema or urticaria, are annoying, but, being unattended with danger to life and without serious consequences they do not contra-indicate the use of the serum

The principal conclusion to be drawn from this able and timely article of Welch's is this, that the results of the treatment of over 7,000 cases of diphtheria by antitoxin demonstrated beyond all reasonable doubt that anti-diphtheric serum is a specific curative agent for diphtheria, surpassing in its efficacy all older methods It is therefore the positive duty of the physician to use it

Welch concludes his study with saying that the discovery of the healing serum is entirely the result of laboratory work, that it is an outcome of the studies of immunity and that the discovery was in no sense accidental "It should be forcibly brought home to those whose philozoic sentiments outweigh sentiments of true philanthropy, that these discoveries which have led to the saving of untold thousands of human lives have been gained by the sacrifice of the lives of thousands of animals, and by no possibility could have been made without experimentation upon animals"

THE PARASYPHILITIC NEUROSES

Whatever the syphilographers may say, the opinion is growing among neurologic specialists that a number of disorders of the central and peripheral nervous system that have up to within a recent period been attributed to other causes, are, in the great majority of cases at least, to be considered as the late results of syphilitic infection First among these are to be counted locomotor ataxia, which careful and reliable observers like Erb, Dejerine, Marie and others find to have been preceded by specific infection in at least 90 per cent of all cases, and paretic dementia, which has, according to the latest reliable statistics of Regis, Savage, Kowalevsky, Hougberg and others a hardly less percentage of similar antecedents, and which Möbius goes so far as to say will only be met with in those who have previously had syphilis Then we have the special type of progressive muscular amyotrophy described by Raymond, which seems to be always preceded by syphilis, to say nothing of the large numbers of cases of neurasthenia, epilepsy, etc, that follow syphilitic infection at a more or less late period and for which no other rational etiologic factor can often be discovered

All of these disorders are treated of by Fournier in a work ("*Les Affections Parasyphilitiques*," Paris, 1894,) that appeared last year, but that has not received quite all the attention it merits The reputation of its author as a syphilographer, belonging rather to the camp of those who seem the less inclined, as a rule, to admit the connection of syphilis with these disorders, ought to give the work much more weight than would otherwise be allowed it, and the additional fact that he has frankly admitted a change of view from that formerly held by him should in no way disparage it Perfect candor should be universal in science, but it is not yet so absolutely commonplace that it is unjustifiable to commend it In matters incapable of accurate mathematical demonstration there is always room for a play of prejudice, for the selection of acceptable and the rejection of objectionable facts It is perhaps in part due to this, that the acceptance of the syphilitic origin of these disorders is so limited as yet, syphilis is an objectionable disease and it is not satisfactory to have to attribute to it disorders that have heretofore been supposed to have other origins

The arguments employed against this view are principally two, first, that the lesions of syphilis are absent, and, second, that the inefficiency of specific treatment is an evidence that the affections are not of a specific nature The weakness of both of these is well shown by Fournier in his reference to the pigmentary syphilide, which is commonly reckoned among the tertiary manifestations, as a typical instance of a parasyphilitic affection It is a little remarkable, however, that in his review of the evidence of the parasyphilitic nature of paresis, he lays no stress on the not infrequent phenomenon of conjugal paresis, husband and wife both affected simultaneously or in succession with the disorder, though, as is quite often the case, without any admission of syphilis by one or both parties This common difficulty of obtaining the facts as to syphilis gives a special value to the statistics on which the belief in the parasyphilitic nature of these affections is based As regards this particular disorder, it is safe to say, from common clinical experience, that the positive testimony invariably understates the facts The fact that the lesions, so far as known of these conditions, are not syphilitic proves nothing, as it is only asserted that they are parasyphilitic, connected with syphilis, a remote consequence of the infection not

Jersey, offered amendments to the Code, just such in part as had been indefinitely postponed These amendments were properly admitted and placed on file for action at the Baltimore meeting But lo! at Baltimore a new parliamentarian is in the chair and new and unwarranted rulings are rendered

After postponing indefinitely all amendments to the Code, like amendments were again offered The Chair ruled that it was out of order to offer like amendments to those postponed at this meeting Herein he was wrong and everybody who sustained him was wrong As I understand it, Dr Priestly offered an amendment that was to lie over until next meeting according to the law He had the right to offer amendments at that meeting couched in the identical language of the amendments postponed He would have the right to re-introduce the same amendments at each meeting for the next forty years if they were defeated thus often Re-introducing an amendment in this manner does not revive action at a given meeting on a matter that has been indefinitely postponed There would be no action whatever taken on re introduced amendments but to state the same to the assembly and place them on file

The judgment of some of the members who so pertinaciously oppose any revision of the Code has been slightly warped, insomuch that they deem any tactics warranted, whether regular or irregular, in order to down "Banquo's ghost" One eminent member used the following unwarranted argument "The *only way* in which subjects of the same character can be re-introduced at this meeting, after having voted for indefinite postponement, is to vote a reconsideration of the vote of postponement, and then we will get that before us" This argument was made against the reintroduction of an amendment by Dr Priestly

The language just quoted is correct parliamentary law when properly applied, but it was not applicable to the case in hand A motion indefinitely postponed by a deliberative body is forever dead unless revived at that same session by a vote to reconsider There being no vote to reconsider, carried, then the only method by which the same subject can be brought before the body, at a subsequent session, is by offering it anew, the same as on former occasions, and that can be done immediately in any case which must necessarily lie over to a subsequent meeting for action

Possibly, since our parliamentarians are growing in knowledge, by next year it will be ruled that, when a question has been indefinitely postponed, it can *never* be revived or reintroduced Who can tell? Cushing and Roberts "are not in it" Such decision would be a boon to the veterans who have assumed the task of handing down the creed to future generations just as it was delivered to the saints from the pen of the immortal Percival They could then sleep in peace

Let us have correct parliamentary rulings at the meetings of our Great AMERICAN MEDICAL ASSOCIATION

A C SIMONTON, M D

Another Side of the Life Insurance Question

LA FAYETTE, IND, Oct 2, 1895

To the Editor —Allow me to call attention to the communication of Dr John L Davis, Medical Director of the Union Central Life Insurance Company, Cincinnati, which appears in the JOURNAL of September 23, page 524, in order to speak briefly in behalf of the members of the common herd in the profession who are interested directly and indirectly in the subject of professional work for life insurance companies I am glad that the Doctor has discussed, in a public way, the practical side of the life insurance question in its relation to the medical profession, for I do not know of any one professional topic that needs it more

The perusal of the Doctor's article gives me the impression that its author is only practically familiar with the whole question theoretically, and that his opinions and estimates of the local examiner have been affected, if not infected, by the gossip and statements of interested, and in some instances, of unscrupulous agents Frequent meetings with examiners, socially and professionally, at varying intervals, has led me to believe that they do not exercise their powers of speech as frequently and freely in the interest of truth and a good all-round understanding as often and as thoroughly as they ought to, because they think it injudicious in a business way to do so, they are so dependent on the agent for position and business

As to the Doctor's paper With his observations and statements as to the scope and purposes of a complete practical physical examination, I have nothing to say

First, then, let me direct attention to the commercial phase of the subject and his statement, "that while physicians are receiving as fees from insurance companies and cooperative associations about $2,500 000 per annum, they are not in every instance giving a *quid pro quo*" The statement that the local medical examiner does not in *every* instance give an equivalent in work for the fee paid is, no doubt, true, but the paper would have been more instructive to all of us if it had stated what per cent of examiners failed to furnish satisfactory reports of their work, or failed to do good valuable work, and specified wherein their reports were defective

In view of the statement in the paper of the expenditure of such a large sum of money, I would like to ask what proportion of the $2,500,000 the Union Central Life Insurance Company pays its local medical examiners? What per cent of this large sum of money goes to the local medical examiners and what to the medical director? As the late Dr McIlvaine, of Cincinnati, would say "Let us have the facts" Detached general statements, like the one cited, prove little if anything, they are unsatisfactory

Since nearly all firstclass life insurance companies pay the examiner $5 for each applicant examined, and the Union Central, Dr Davis' company, only pays $3, I think the citation in this connection against the local examiner is not altogether timely, if fair

The local examiner frequently finds it a very difficult undertaking to "fully sympathize with the agent," when that individual makes himself a disagreeable visitor in his office as he sometimes does, or when he solicits, hints that his company wants, yes, expects him to take out a policy "with us," and to let the physical examinations of applicants pay the premiums, or when he objects loudly, offensively it may be, to the examiner's record of facts, etc, etc, in a given examination As a class, solicitors for life insurance are gentlemen, but the most uncivil man I ever met in a business way was an agent for a life insurance company If an agent is disagreeable or seeks to obtain an advantage for his company through the examiner, the latter is sure to come in for a share of abuse and misrepresentation, for the interests of the examiner and agent in the presence of a difference lie in widely divergent directions

The defective work done for the Union Central Life Insurance Company by its local medical examiners is probably due, it seems to me, to the low fee paid by the company Three dollars, the fee allowed for a complete physical examination of applicants for insurance with the company he represents can hardly expect to secure firstclass professional talent, or if it does secure it, to expect it to exercise "the greatest tact and skill in drawing out and properly weighing every feature required for a perfect report" Is it natural to expect a qualified physician to be at all times "tactful and approachable, willing to display a sympathetic *camaraderie*, putting the applicant at his ease, and by his manner, if not by word, commend the applicant's motive in taking insurance incidentally perhaps speaking well of the company and a good word for the agent?" "The examiner must honestly and earnestly believe in insurance and his company, and must fully sympathize with the agent in his difficult task" Can a firstclass physician do all this for each applicant and be accessible for such work at all times, and do it honestly for $3 and not sacrifice his dignity in some degree as a physician in Dr Davis' estimation?

Knowing that his neighbor examiner receives $5 for an examination for his companies, the examiner for the Union Central Life Insurance Company feels that he is not fully appreciated, that the company takes an advantage of him, obliging him to work for less than he is worth, for less than the work is worth if it is done "honestly and earnestly" An old physician, independent, positive, original, told me lately that he always gave the insurance company that brought an applicant to his office for examination for $1, one dollar's worth of work and no more, for $2 or $3, work in proportion to the fee and no more Of course this remedy is impracticable, even dishonorable, and could not for a moment be held up as a rule of action against the wrong

The AMERICAN MEDICAL ASSOCIATION has declared that the fee for each complete physical examination for life insurance *should be $5, and not $3, as the Union* Central Life Insurance Company obliges its local medical examiners to accept or go out of its service

I have wondered if the above statements would not furnish a partial explanation, if not a complete one, of the discussion of "The Fool Doctor," by the underwriters of his *company in convention, and if their discussion of this subject* in his presence was not a mute appeal to him to employ *at the customary rates, firstclass discreet physicians* for local medical examiners

Is not the fee for work for each applicant examined, that is, the *honorarium*, the mark and degree of business or professional esteem in which the examiner is held by the company? If Dr Davis will look into the home office of his company thoughtfully and *judicially* he will no doubt discover the chief cause of the ills which he describes so graphically in his paper, and which caused the agents to ridicule members of his profession, and, having discovered it, the remedy will readily suggest itself

Finally, permit me to inquire if the small fees paid physicians for professional work nowadays by insurance and railroad companies are not one of the leading causes for the unsatisfactory social position of the medical profession in this country? Small fees, too, I think has much to do in dividing medicine into many specialisms for gain rather than for study or investigation, as well as creating the army of self selected specialists regulars as well as irregulars

Yours respectfully, W W VINNEDGE, M D

Blood Poisoning—Alcohol

ORAN, MO., Sept 30, 1895

To the Editor —To write a readable article on blood poisoning requires considerable medical knowledge and a very vivid imagination Witness recent articles in the JOURNAL Many maladies come within the scope of this heading All contagious diseases (and many non contagious) So does la grippe, malaria, pneumonia, etc The field is large and there is much speculation along this line

The ancient medical philosopher believed in blood contamination and wrote much in defense of his belief To say that he drew largely on his imagination is to put it very mildly The modern physician is in the same category He believes in blood poisons, too, but he thinks it silly to say of him that he does not know exactly what he is talking about when he uses the term He can (so he thinks), point out the particular poison in each case He calls these poisons, *germs* And by the aid of his microscope and his imagination, he gives each germ its form and other characteristics by *which it can be known* He will also, without being asked, tell you how these poisons originate how they act, and how to get rid of them But when he has a case to treat and reports results, it seems that it takes him just as long to relieve the case as it does one who does not claim so much and such wonderful knowledge If driven from his position on the germ theory, he begins to talk learnedly of ptomaines and leucomaines, he will tell you that it requires an expert in the use of the microscope to discover and analyze germs, but that he is able to see and analyze the *debris* of these so-called disease producers

One doctor insinuates that he, by examination of the urine, can tell what effect alcohol has had in a given case Much is being written in condemnation of alcohol as a remedy Why? Not because it is harmful as a *remedy*, but because it does so much harm as a *beverage* Alcohol is condemned because it is not a "tissue builder," not a "stimulant," not a "food," but a "paralyzer" Antifebrin is not a tissue builder, nor a stimulant, nor a food, but a paralyzer Chloroform, ether, chloral and a host of other remedies all belong to the same list I see mercury is recommended for alcoholic rheumatism I wonder if alcohol would not be *good for mercurial rheumatism? Is mercury a tissue* builder, a stimulant, or a food? Neither, but a very useful remedy nevertheless

Now to the subject again Alcohol in large (poisonous) quantities poisons the blood, *en masse* So does morphin, chloral, chloroform, iodin and a host of other poisons The old time doctor knew this, and he undertook by the use of the lancet to remove the blood and with it the poison He also knew that poisons were removed *from the system in* gaseous form from the lungs, in fluid form from the skin and kidneys, and in solid form from the bowels—hence his frequent use of expectorants, diaphoretics, diuretics and purgatives He also discovered that *one poison would sometimes* neutralize another, not because they were animals that would fight and destroy each other, as the modern writer would have us believe, but by a chemic process they were made harmless The modern writer would do so much better if he "did not know so many things that were not so"

I wish to correct the writer who teaches that drunkards are made in the sick room Most drunkards are such, long *before they get sick* Alcohol is not being prescribed too much by the regular profession Drunkards prescribe and use it for all kinds of maladies It has a legitimate place in medicine Its worst enemies among the profession admit that it is a pain obtunder As such, it has few equals It is transient in its effects in medicinal doses—is quickly *thrown off from the lungs, skin and kidneys*, promoting the action of each In larger quantities it neutralizes other poisons and aids in ridding the system of them Much of the good effect of fluid extracts is because of the alcohol they contain Alcohol, as a remedy and a preserver of other remedies, has come to stay I have no objection to the fight that is being made against intemperance—I am a total abstainer—but I shall prescribe alcohol whenever I think it is *indicated*, never for well people, but in all cases of sickness for which it is needed The harmful effects so abundantly portrayed by writers for the JOURNAL, are those of drunkenness combined with starvation, vice, exposure and other calamities that befall the drunkard

The reader will do well to look after *excretion* in all cases where the blood is contaminated Do not forget the known antidotes, and do not believe everything you see written in the JOURNAL It is much easier to guess than to know, and writers are too much given to telling plausible stories not founded upon facts The germ theory, with all its concomitants, has got to go It has been "weighed in the balance and found wanting" Its adherents, like those of the lancet, will have to take a back seat

Respectfully submitted, W P HOWLE, M D

New York Pasteur Institute

NEW YORK, Oct 1, 1895

To the Editor —In perusing the JOURNAL for August 10, I find an account of a visit to the Pasteur Institute of Paris, by Dr Casey A Wood in which he writes, on page 250, as follows

"By the way, Chicago is the only Pasteur station except, I believe, Havana and New Orleans marked on the large map of America at the Institute I could not discover why New York, with Gibier's *station had been omitted*"

Will you allow me to remark in answer to this note that when the map above mentioned was made, there was no station either in Chicago or New York, but at the Pasteur Institute it had been said that a station was going to be started in Chicago *For some reason or other*, no institution was started at the time in Chicago, but a special mark was made on the map indicating that there was a station there It was only about two years later that I started the Institute in New York, and six months afterward Dr Lagorio started another in Chicago, but since, no change has been made on the map However, to avoid any comment on this matter, I hope that the Directors of the Paris Institute to whom I have submitted the facts, will make the necessary addition upon this map Yours truly, PAUL GIBIER

It was Dr Fish, and not Dr. Burgess

MILWAUKEE, WIS, Oct 5, 1895

To the Editor —In your issue of the 5th inst, you state on page 578 that Dr A J Burgess of Milwaukee said "so and-so" These remarks, abbreviated though they be, were mine I believe I am the only Fellow of the American Association of Obstetricians and Gynecologists in this State—and at least the only one present at this discussion I most decidedly object to your quoting some one else for me, or your attributing remarks to me made by another

Yours truly, E F FISH, M D

The McDowell Biography

NEW ORLEANS, Oct 4, 1895

To the Editor —Some time ago, over one year, a lady came to my office soliciting subscriptions to the biography of Ephraim McDowell, M D, claiming among other things, that she was a distant relative of the Doctor I find my receipt for the price of said book, but no book yet I do not believe the Doctor would approve of such slow treatment or action As I have not her address, and I noticed some time since you had, would you kindly send this to her, or to those in charge of publication, and oblige, S L HENRY, M D

Some Recent Comments on the Journal

THE OPINION OF AN OLD MEMBER

LE MARS, IOWA, Sept 8, 1895

To the Editor —Your publication of letters on the line of "What I know about the JOURNAL," is correct, and some of the criticisms are good There is an abundance of medical periodicals of the "featherweight" variety in existence, such as would suit quite a sprinkling of our profession, but for physicians who are eligible to membership in the AMERICAN MEDICAL ASSOCIATION, a journal like ours is not too scientific or too heavy If all those who now disagree with me will but read the JOURNAL for a few months, they will soon feel the necessity for that class of medical literature A page or two each week of light practical reading, as suggested by Dr Towler, would certainly not be considered amiss by any one, and might make the JOURNAL more popular with some As long as we have our editor to act as sifting committee, there will be no danger of articles finding their way into the JOURNAL which would make it a laughing stock to the profession or to other periodicals I have in my library every issue of our JOURNAL, from No 1 to the present, and could not spare a single number PAUL L BRICK, M D

FROM A HEALTH OFFICER

WOOSTER, OHIO, Oct 1, 1895

To the Editor —What seemed more than an herculean task a few months since—and it was even doubted whether it could be done—the editing of the JOURNAL, is now grandly accomplished The JOURNAL to day is the best educator the profession in America has ever had

Glance over the articles it has contained for three or four months last past! Many of them are exhaustive on the subjects they discuss, and some bring to light new truths of great value to the profession

Accept my congratulations for your past success and my earnest wishes for your future usefulness Fraternally,

JOSEPH E BARRETT, M D
Health Officer

HE COMPLIMENTS THE JOURNAL

COLUMBUS, OHIO, Oct 5, 1895

To the Editor — Permit me to compliment you on the JOURNAL in general, and particularly on your editorials The editorial of two weeks ago on Basedow's disease I think especially good While you did not solve the secret of the etiology and seat of that mysterious malady, you presented all that is known in a condensed and scholarly manner

STARLING LOVING, M D

DR QUIMBY'S OPINION

To the Editor — As time rolls on, our JOURNAL grows in value and importance, and if no obstacle is thrown in the way, is destined to be one of the greatest medical lights and journals of the age I N QUIMBY, M D

NECROLOGY

JOSEPH C GORDON, M D, of Mt Vernon, Ohio, October 2, aged 54 He was born in Chester County, Pa, and went to Knox County, Ohio, in 1858 He served through the Civil War in Company A, 20th Regiment O V I, and was prominent in Masonic circles ——Wm H Gibson, M D, of Chariton, Iowa, October 3 ——E P Gaylord, M D, of Alameda, Cal, September 27, aged 61 He was formerly from New York and had lived in Alameda nearly three years ——F M Everett, M D, of Corydon, Iowa, September 29, aged 65 ——James Collins, M D, of Philadelphia, October 7

PUBLIC HEALTH

Pollution of the Passaic River, New Jersey —According to the *Sanitarian* for August the health authorities of Passaic, N J, have passed resolutions declaring that the pollution of the Passaic River by sewage and manufacturing refuse from the cities of Passaic and Paterson has reached the danger point Every summer, City Physician Terhune says, there is an epidemic of malarial fevers among the residents along the river and the Dundee Canal, which the river supplies The board called on the two cities to take steps to diminish pollution The board advocates the building of a trunk sewer from Paterson to the sea

Cost of Cremation in New York —The charge for cremating the body of an adult in New York city is $35 and for that of a child $25 Urns or vases vary in price from $6 to $45, the former are of bronze and white metal, the latter of serpentine stone, marble, etc For $25 a niche may be bought in the crematory where the urn will be cared for, or it may be taken possession of by the family About one-half are said to be kept at the crematory, some are taken away and placed in safety deposit vaults and others are kept among the most sacred treasures of the home A newspaper report has it that one relict carries the ashes of her deceased husband wherever she goes—to Europe and back several times and frequently to the seashore and mountains It is not stated what rate of fare is charged for the "remains"

The New York City Board of Health's New Regulations —The New York Board of Health has adopted rules for the prevention of the spread of contagious diseases among public school children These rules decree that slates and slate pencils shall be abolished, and pens and pencils substituted, the latter to be kept in separate boxes by each pupil All the school property of a child ill with a contagious disease shall be turned over to the health board Books that are taken home shall be re covered with brown paper once a month Each class must have its own covered pitcher for drinking water, and each pupil a separate cup In cases of contagious disease in a family, the children are at once to be excluded, and teachers are to report weekly to the board the names and conditions of pupils who are ill All teachers and principals shall be forbidden to send any pupil to the home of another pupil for any reason Circulars of instruction to the Board of Education on those matters, and also to principals, are in the course of preparation

Another Attack on American Live Stock —A London cable dispatch of the 5th inst , reports that the English agricultural papers are raising an outcry against the free admission into Great Britain of American sheep A recent consignment of sheep from America was found to be suffering with scab, the spread of which disease in the United Kingdom is due, according to the *Live Stock Journal*, to the importation of sheep from the United States Many of these sheep were dispersed over the country for grazing and they spread the disease The paper says that the Board of Agriculture must therefore be asked to issue an edict, similar to that applied to cattle, providing that American and Canadian sheep shall be killed at their port of landing Secretary Morton will investigate the foundation for the charge, which will probably be found to have its origin—as in other legislation hostile to American food products—in purely commercial reasons and not in any keen concern for the public health

Dr Dana on the Saddle —Upon what shall the rider sit? With all the world a-wheel this is certainly a question fundamentally touching the public health, and our esteemed confrère, Dr Charles Anderson Dana of *The Sun*, who has so long been in the saddle in more than one sense, discusses it in his usual profound and instructive fashion Especially is he concerned about the proper saddle for women He points out that in this feature of the bicycle's construction the pommel is high, it interferes with the dress and chafes the body, and if this part is tilted downward one slides forward on to the narrow shank of leather and the comfort of wheeling is destroyed , stout women condemn the narrowness of most saddles, while many of less weight object to a seat of more than ordinary width , out of fully a score of saddles that are satisfactory to men, not one is pronounced good by the mass of women , not one, they say, is adaptable by any possibility to woman's structure , in short, while the saddles of to-day suit wheelmen, they positively do not suit wheelwomen, and hence they must be condemned Dr Dana then proceeds to consider the essentials of a perfect bicycle saddle for either man or woman 1, one that shall maintain the body in an easy and proper position , 2 one that shall afford the rider a firm, yet elastic, seat , 3, one that shall allow pedaling without needless friction The cycling sisterhood do not demand a saddle with upholstered arms in which to recline at will, but one conforming to their bodily requirements, and from which the machine may be propelled with facility and comfort " In these days of reform will not," he asks, ' some one of our fair readers with masculine ingenuity and feminine sense of personal comfort, invent a reformed bicycle saddle? We shall hail the advent of so important a factor to our sisters seeking health and pleasure on the wheel "

A Report on Malarial Fever in New Jersey —According to *Public Health*, August, Dr J C Smock, the State Geologist for New Jersey, has summarized the facts as to the origin and means of preventing malaria in New Jersey under the following heads 1, malarial fevers prevail over that part of the State which lies north of the terminal moraine, wherever the conditions are favorable to it 2, there is a remarkable absence of malaria in the country south of the terminal moraine, excepting localities and districts of limited extent, where aggravated conditions of its determination exist , 3, the existence of malaria is not necessarily due to a geologic formation, but to a sub surface condition, common in the country which is north of the terminal moraine, and covered more or less by glacial drift , 4, the element of imperfect or disturbed under drainage is a more potent condition in determining malaria than any other , 5, the thorough under draining of a district or tract is the most practicable and most effective means in order to amelioration and protection , 6, the distance to which the malarial poison may be carried by winds or air currents is comparatively short, and not over hills and mountains miles away, as often popularly stated , 7, belts of forests, and even hedges, tend to arrest this conveyance of malaria by winds One instance was cited where, in the northern part of the State, a hedge is reported to have prevented malaria The hedge was cut down and the whole family was taken sick with malarial disease The occurrence of malaria or its distribution areally in New Jersey seems to be explained by these conditions of sub surface drainage and the essential factors of heat, moisture, and dead vegetation, and not by wind transmission, otherwise there would be greater uniformity in the occurrence, instead of the irregular distribution We have here a fever stricken locality, and there an area free from it Referring to the Great Meadows of the Pequest Valley, in Warren County, the testimony of intelligent laymen there resident led the writer to believe that there is no malaria there Formerly this valley was "full of it," as one said, "nearly every one had the shakes" The beneficial effects are attributed to the lowering of the bed of the Pequest River and the more rapid delivery of its waters Where formerly were wide spread inundated lands and a sluggish stream with scarcely a perceptible current there are to day productive gardens and a swift current The possibility of future outbreaks was suggested by the writer until the whole tract has its ground-water lowered sufficiently to make a well drained soil and subsoil, as well as a thorough surface system of drainage

Health Reports —The following health reports have been received at the office of the Supervising Surgeon General, Marine Hospital Service

SMALLPOX—DOMESTIC

Louisiana New Orleans, September 21 to 28, 11 cases, 1 death

Michigan Smallpox reported at Battle Creek, Battle Creek Township, Bedford Township, and Detroit

Nevada Carson, September 15 to 17, 15 cases

SMALLPOX—FOREIGN

Cairo September 3 to 9, 2 deaths
Calcutta August 17 to 31, 2 deaths
Buenos Ayres July 1 to 31, 24 deaths
Barcelona August 1 to 31, 8 deaths
Dublin, September 14 to 21, 5 cases, 1 death
Gibraltar, September 8 to 15, 1 case
London, Eng September 14 to 21, 2 deaths
Montevideo August 3 to 10, 1 case , August 17 to 24, 4 cases, 1 death
Naples September 14 to 21, 3 cases, 3 deaths
Odessa September 7 to 14, 1 case
Prague September 7 to 14, 2 cases
Rio de Janeiro September 3 to 10, 81 deaths
Tuxpan September 7 to 14, 3 deaths
Warsaw September 1 to 14, 2 deaths

CHOLERA

India Bombay, August 27 to September 1, 8 deaths Calcutta, September 17 to 31, 17 deaths

Tangier September 15 to 21, 79 cases, 46 deaths

Austro-Hungary Tarnopol September 3 to 9, 14 cases, 5 deaths , Tarnopol District, September 2 to 9, 3 cases, 1 death , Brody District, September 1 to 2, 1 case, 1 death , Robatyn District, September 2, 4 cases, 4 deaths

France Paris, September 1 to 7, 1 case, 'choleriform affection "

Russia Volhynia Government, August 4 to 10 1,004 cases, 822 deaths , August 11 to 17 2,025 cases, 718 deaths , August 18 to 24, 2,497 cases, 944 deaths , August 25 to 31, 3,352 cases, 1,190 deaths

Cases are also reported from districts of Ostrog, Kremenetz, Saslow, Starokoustantinow, Nowogradwalyuski, Dubno, Rowno, Luzk, Shitonir and Kowel

Turkey Aleppo August 21 to September 4, 35 cases, 18 deaths , Brussa (city), August 29 to September 1, 88 cases, 37 deaths , Brussa (vilayet), August 24 to 30, 32 cases, 16 deaths Diabekir (vilayet), August 24 to September 1, 77 cases, 77 deaths , Adana (vilayet), August 23 to 27, 1 case, 2 deaths

Japan April 18 to 30, 99 cases, 28 deaths , May 1 to 31, 665 cases, 514 deaths , June 1 to 30 3,573 cases, 1,931 deaths , July 1 to 31, 7,575 cases, 4,891 deaths , August 1 to 2, 810 cases, 553 deaths

YELLOW FEVER

Cuba Cienfuegos, September 22 to 29, 8 deaths , Havana, September 19 to 26, 70 cases, 22 deaths Sagua la Grande, September 14 to 21, 4 cases, 1 death

Mexico Vera Cruz, September 19 to 26, 4 deaths

Brazil Rio de Janeiro, September 3 to 10 7 deaths

MISCELLANY.

Addresses Wanted—Dr F Meyer, JOURNAL returned from Baltimore, Md Dr M Perl, JOURNAL returned from Houston, Tex Dr L Smith, JOURNAL returned from Chattanooga, Pa

South Dakota Blind Asylum—The Legislature has established an institution to be known by the foregoing name and located at Gary, in Deuel County The State Board of Charities and Corrections are to have charge of it and of the employment of superintendent, attendants and instructors

Massachusetts Pharmacy Laws to Be Codified—A resolution was passed by the General Court, or Legislature, of Massachusetts, providing that the board of registration in pharmacy cause to be codified, consolidated and arranged, all laws now in force relating to the regulation or practice of pharmacy, and all laws which it is the duty of the members of the board of registration in pharmacy to enforce Such codification, consolidation and arrangement shall be reported to the general court on or before Jan 1, 1896

Anti-American-Alliance Serum—The epidemic that is carrying off so many of the English titled "eligibles," who fall a ready prey to American beauty and bullion, leads London *Truth* to offer this delusive hope to the British matron with daughters of her own to marry off "After years spent in laborious and learned research, Prof Padmore Brown claims to have discovered a serum, a hypodermic injection of which will preserve young men of position against marrying Americans If the serum really possesses the property which the Professor declares it has, this will undoubtedly be one of the most important discoveries of the century No mother with eligible daughters and no unmarried woman would, in that event, ever be without one of the hypodermic syringes filled to the nozzle with anti-American-alliance fluid"

Provision Made for North Dakota Blind Asylum—The Legislature of North Dakota at its last session established a blind asylum, to be located at Bathgate, that State The government thereof is vested in a board of five trustees, to be nominated by the Governor and confirmed by the Senate The 30,000 acres of land donated by Congress for the purpose of such blind asylum and appropriated by the constitution of the State for it, and all moneys received from the interest and income derived from the sales of such lands or rents derived from the leasing of such lands, are appropriated for the construction and maintenance of this asylum

Synthetic Alcohol.—Now that acetylene can be made industrially upon a cheap scale, the question of preparing alcohol synthetically is again being agitated Indeed Caro (*Pharm Centralb*), while finding previously published methods insufficient, claims to have devised a process which eventually may lead to the desired results He passes acetylene through concentrated hydriodic acid, thereby obtaining nearly 60 per cent of CH_3CHI_2 This, when boiled with concentrated solution of potassium hydrate, yields alcohol, acetylene and potassium acetate —*Western Druggist*

Methyl Salicylate in Senega Root—Rubner having noticed (*Pharm Jour*) that a certain sample of senega root had a distinct odor of gaultheria, attributed this to sophistication, but Goldener states that, under certain conditions, many plants of the polygalaceæ contain methyl salicylate, and therefore the supposed adulterant is a natural constituent of the root C Dunnenberger points out that the Swiss pharmacopœia has adopted the salicylic acid in senega root as a test of identity, thus asserting its existence as a normal constituent of the root —*Western Druggist*

Society Notes.

THE annual meeting of the Minnesota Academy of Medicine was held in St Paul, October 2 The following officers were elected for the ensuing year President, A E Senkler, St Paul, Vice-President, W A Jones, Minneapolis, Secretary, R O Beard, Minneapolis ——At the annual meeting of the Tri-State Medical Society held at Des Moines, Iowa, the following officers were elected President, D C Babcock, Chicago, First Vice-President, A H Cordier, Kansas City, Mo, Second Vice-President, W A Todd, Chariton, Iowa; Secretary, Geo Cole, St Louis The next meeting will be held in Chicago ——The first annual meeting of the Utah State Medical Society was held in Salt Lake City October 1, under the presidency of Francis L Bascom ——The Utah County Medical Society was organized in Salt Lake City September 28 The following officers were elected President, W E Pike, Vice-President, M H Hardy, Secretary and Treasurer, F W Taylor

Cleveland Notes

THE students of the junior class in the Medical Department of the University of Wooster at Cleveland have organized a "Pathological Journal Club," which has for its chief object an instruction in the methods of literary research by bringing the students into contact with the current literature bearing upon pathology and bacteriology in connection with their required class-room and laboratory instruction in these subjects

At the first meeting of the club, held Thursday evening, October 3, Mr Morris Schott read his detailed translation of a paper upon "The Etiology of Rheumatic Tetanus," by Carbone and Perrero, which appeared in the *Centralblatt für Bakteriologie* of August 31, 1895, Mr J J Fleming read an abstract of "Notes on Bacillus Coli Communis and Related Forms," by Theobald Smith, from the *American Journal of the Medical Sciences* for September, 1895, and Mr R G Schnee gave an abstract of an article by E O Jordan, "On some Conditions affecting the Behavior of the Typhoid Bacillus in Water," from the *Medical News* of Sept 28, 1895

The club elected Dr A P Ohlmacher president, and Mr A L Smith secretary The meetings will be held bi-weekly

Louisville Notes

G A R REPORT—The report of the Medical Director, Dr W H White, of the workings of his department during the National Encampment of the G A R has been submitted to the Citizens' Committee The workings of the department have been recorded in these columns previously Reports were returned each day by the various chairmen in the different wards, giving the name, residence, post, disability, where quartered and what disposition was made of the patient From these reports it appears that 284 cases were cared for; 98 of these occurred during the grand parade day, being prostrations from the excessive heat It is a great wonder that many more of the old veterans did not succumb, as the thermometer reached the 98 degree mark, and the sun beat down from a cloudless sky Thirteen were cared for at the fireworks, mostly bruises from an accident to the seats erected on the river front, and thirty were prostrations at the barbecue The expenses of the medical department amounted to $556 98, quite a balance being left over from the liberal allowance made by the Board of Control It is gratifying to announce that not a single death occurred during the Encampment, and not a single case of serious sickness or injury among the veterans occurred A most deplorable accident was that which befell the members of the Louisville Legion A squad of men were placed in charge of a gun which was to fire the salute of welcome While proceeding to the selected site, the caisson exploded, and three of the Legion men were killed, and the negro driver They were almost blown to pieces, and beyond recognition

NULL—Dr C W Null died at the City Hospital on the 26th inst He was 42 years of age, having come to Louisville from North Carolina He secured a position as janitor of the Louisville Medical College, and at once began the study of medicine, graduating in due time, and shortly after being elected to the professor of physiology Later, he lectured on materia medica At this time he began to drink, his fall was as rapid as his rise, and he was taken from a saloon, unconscious, to the City Hospital, where he died

LOUISVILLE ACADEMY OF MEDICINE—The regular meeting of this society was held in the Academy rooms Monday evening, September 30 The subject for discussion was 'Texas Fever," introduced by a paper by Dr Cashin

Death Report —The total number of deaths for the week ending September 28 was 72, 41 male, 56 white, 4 died at the City Hospital 3 stillbirths, 10 deaths from typhoid fever 6 from inanition and 6 from cerebral meningitis

American Public Health Association —The President of this Association, Dr Wm Bailey, accompanied by Drs W L Rodman, J M Mathews, President of the State Board of Health of Kentucky, and Dr Carl Weidner, attended the meeting at Denver on the 28th ult

Kentucky School of Medicine —The catalogue of this school for the session 1896 is just out, and shows the following new appointments upon its staff Dr J W Guest, assistant in gynecology and abdominal surgery, Dr Wm P Banta, assistant in the laboratory of surgery, Dr Gavin Fulton, assistant in physiology, Dr Florence Brande, assistant in clinical medicine, Dr Henry H Koehler, assistant in clinical medicine Dr Carl Weidner became associate professor of the practice of medicine, and director of the laboratories of histology, pathology and bacteriology, Dr Henry E Tuley is made an instructor of physical diagnosis, in addition to his charge as chief of medical clinic The election of Dr S E Woody as Dean was mentioned in a previous issue

St Louis Notes

Health of the City —The mortuary report for the week ending October 5 gives 172 deaths, 10 less than during the preceding week, and 29 more than in the corresponding week of 1894 Death rate, 16 per 1,000 There were 27 deaths under the age of 1 year, 48 under the age of 5, 27 deaths were due to zymotic diseases During the week 121 cases of diphtheria and 6 cases of croup were reported, with 15 deaths, 8 cases of scarlatina without mortality, 11 cases of typhoid, with 2 deaths, and 1 case of measles The prevalence of diphtheria is still causing alarm, and the public seems more alive to the need there is for a strict compliance with the instructions of the Board of Health

The St Louis Medical Society —At the meeting of October 5, Dr Sherwood Dunn, late of Pozzi's clinic, demonstrated Professor Richelot's operation for vaginal hysterectomy to an appreciative audience

Free Dispensary Abuses —The city has opened a branch dispensary, and *apropos* of this extension of facilities for medical aid, there is renewed discussion of the abuse of this privilege of charity Plans are proposed looking to the restriction of this charity in the case of the city dispensaries, which are easy of accomplishment, but the abuse of free college clinics is not so easily reached The college is anxious to obtain a sufficiency of clinical material, and is never discriminative in its acceptance of cases, The multiplication of colleges in the city has greatly increased the number of free clinics, and it has now become notorious that a large proportion of the cases seeking aid in them are persons coming from both city and country who are able to pay It is to be hoped that the State Board of Health will hit upon some plan to curtail this evil, which harms the profession quite as much as a superfluity of its own members

The Missouri Medical College —Tuesday, October 1, the new college building was turned over to the trustees, and dedicated with ceremony The new building is situated on Jefferson Avenue, near Washington, and adjoins the old Polyclinic "The building is faced with white limestone, designed in the classic style of architecture and is most delicate in all its details At the entrance two lamps of bronze, set on pedestals, give a most artistic effect In the basement are located the boilers, heaters, and electrical plant The system of heating and ventilating introduced forces the heat throughout the building The sanitary system is one of the most important features in a building of this kind and has been handled in a most satisfactory manner On entering the building the spacious hall connects with the rooms, clinic rooms and a spacious lecture hall The surgical amphitheater is located in the adjoining building with easy access from main hall The second floor contains the biologic laboratory fitted up so that each student has his table with lockers Connecting are the professors' rooms The main amphitheater, with a seating capacity of 300, is located on this floor, with a large stage, connecting with the stage are large compounding rooms and smaller laboratories On the third floor is located a large well lighted reading room, the pathologic, bacteriologic and physiologic laboratories The professors' gallery runs the entire length of the rooms and so located that each student has full view of his doings The dissecting hall is located on the fourth floor, with cement floor and all necessary drains and lighted with an immense skylight

The Duestrow Case —The prosecution of this insane uxoricide is still conducted with a zeal worthy of a better cause The latest move of the prosecuting attorney is the announcement of an intention to attempt to obtain an indictment for murder in the first degree before the St Louis grand jury This is the result of the failure to obtain conviction in the August trial in Franklin County To further prejudice the public, the prosecution conducted a farcical examination in Franklin County with a view to unearth bribery of the jurors who served at the last trial It is a sad commentary upon the administration of justice to realize that the public prosecutor has it in his power to affect the course of the law by cunningly playing upon popular opinion There is an outspoken determination to compass the legal execution of Duestrow, sane or insane

Washington Notes

Annual Report of the Health Officer —The annual report of the Health Officer shows the total number of deaths during the last fiscal year was 5 565, of which 3,114 were white and 2,451 colored The death rate was 16 97 per 1,000 white inhabitants and 28 18 per 1,000 colored, and 20 57 per 1,000 of the entire population The decrease in deaths was 474 The deaths from zymotic diseases numbered 1,086, as against 1,398 the preceding year There were 4,794 returns of births made during the year, of which 2,878 were white and 1,916 colored The births fell short of the deaths by 771 Estimated from the increase of population, probably 5,000 births were not reported, although required by law It is gratifying to note, continues the health officer, that at no previous time for twenty years was the death rate so low The marriages reported were 2,891, as against 1,496 the year before Of these 1,411 were white and 980 colored The estimates appended for the expenses of the fiscal year is as follows One health officer, $8,000 One chief inspector, who shall be a physician and act as deputy health officer, $1,800 Fifteen sanitary and food inspectors at $1,200, $18,000 One sanitary and food inspector, who shall be a practical chemist, and inspect dairy products, $1,800 One sanitary and food inspector to assist chemist, etc, $600 Two sanitary and food inspectors, who shall be veterinary surgeons, and act as inspectors of live stock, dairy farms, etc, at $1,200, $2,400 One inspector of marine products $1,200 One chief clerk and deputy health officer, $1,800 One clerk, $1,400 Four clerks, two of whom may also act as sanitary and food inspectors, at $1,200, $4,800 One clerk, $1,000 One messenger and janitor, $600 One poundmaster, $1,200 Laborers at not exceeding $40 per month, $1,920 Ambulance driver, $480 For rent of office and stable, $1,120 For support of chemic laboratory $1,000 For the collection and disposal of garbage and dead animals, $57 000 For the prevention of the spread of scarlet fever, diphtheria and other minor contagious diseases, including the establishment and maintenance of a bacteriologic laboratory and disinfecting service, to be immediately available, $15,000 Contingent expenses, $4,000 For the erection of an administration building, isolation ward, stable, mortuary and discharging room in connection with the smallpox hospital, and for the equipment of these buildings and of those already erected, $15,000 For the relief of the poor—twenty physicians to the poor, at $480 per annum, $9,600, drugs, printing, etc., $3,700

Columbia Hospital Dispensary Chief —The executive committee of the Board of Directors of the Columbia Hospital have appointed Dr Lewis P Smith chief of the dispensary service

Annual Report of the Coroner.—Dr Chas M Hammett, coroner of the District, has presented his annual report for the past year He makes an urgent appeal for the erection of a new morgue, and asks that $12,000 be appropriated for that purpose The new one in Baltimore cost $4,500, and so the coroner estimates $5,000 for the site, $4,500 for the building, and $2,500 for its equipment

THE WASHINGTON BOARD OF TRADE —At the meeting of the Board of Trade this week, the principal matters discussed were the means of prevention of the spread of typhoid fever and the extension of the sewer system of the District

MEDICAL EXAMINATIONS OF PHYSICIANS TO THE POOR —The medical examining board of the District Government held its first examination on the 5th inst to fill vacancies in the staff of physicians to the poor Twenty-five applicants were examined Ten vacancies will exist on December 15 next The names of the successful candidates will be announced later

GEORGETOWN MEDICAL COLLEGE —The chair of surgery has been divided Deputy Surgeon-General Forwood, U S A has consented to give a number of lectures upon such portions of military surgery as will prove of decided interest to the general surgeon He will also treat of surgical pathology and the technique of operations Word has just been received from Prof Ernest La Place, in response to an invitation, that he will lecture on brain surgery Dr Snyder, of Garfield Hospital staff, has been elected an additional professor of surgery Dr Snyder will also lecture at the college upon surgery

Dr John W Bayne, attending surgeon to Providence Hospital, will this year lecture on theoretical as well as clinical surgery Dr Devereux has been elected lecturer on "minor surgery," and will continue his efficient instruction in bandaging and fracture dressing, which made last year's course in practical surgery such a success Dr George M Kober, late of the United States Army Medical Corps, has been elected professor of hygiene and military surgery As an acknowledgment of his ability in hygiene the honorable Commissioners of the District have selected him for the important post of special sanitary inspector to study the cause of the recent epidemic of typhoid fever

The faculty has created the chair of diseases of infancy and children To this professorship they have elected Dr S S Adams The didactic course which he will give will be illustrated by bedside instruction at the Children's and Washington Hospital for Foundlings

The facilities for clinical medicine have been augmented by the election of Dr T N Vincent as professor of clinical medicine He will lecture at Providence Hospital The clinical professors will add to their usual clinics at the appointed hours instruction at the bedside by ward classes To these facilities for clinical instruction additional opportunities will be furnished by other members of the medical staffs of Providence and Emergency Hospitals, as well as the Eastern and Women's Dispensary

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from September 28 1895 to October 4, 1895

Capt Eugene L Swift, Asst Surgeon (Ft Yates, N D), is granted leave of absence for one month, to take effect when his services can be spared with permission to apply for an extension of one month

Lieut Col Joseph R Gibson, Deputy Surgeon General, will report in person to the president of the Army retiring board at Washington Bks , D C , at such time as he may designate, for examination by the board

Capt Guy L Edie, Asst Surgeon, is relieved from duty as assistant to the attending surgeon in the city of Washington

First Lieut Frederick P Reynolds, Asst Surgeon, is relieved from duty at Ft Sam Houston, Texas and ordered to Ft Clark, Texas, for duty, relieving Capt Benjamin L Ten Eyck, Asst Surgeon, Capt Ten Eyck, on being thus relieved, is ordered to Columbus Bks , Ohio, for duty

First Lieut William W Quinton, Asst Surgeon, will be relieved from temporary duty at Ft Logan, Colo , to take effect upon the arrival there of Capt W W Johnson, Asst Surgeon, and ordered to Ft Riley, Kan , for duty

Lieut Col John S Billings, Deputy Surgeon General, having served over thirty years in the Army, is on his own application and by direction of the President, retired from active service this date Oct 1 1895

First Lieut Frank T Meriwether, Asst Surgeon, having been found incapacitated by an Army retiring board on account of disability incident to the service is by direction of the President retired from active service this date

Capt Henry P Birmingham, Asst Surgeon, is granted leave of absence for one month, to take effect upon the arrival at Ft Trumbull, Conn of Capt George E Bushnell, Asst Surgeon

Capt George E Bushnell, Asst Surgeon, will proceed to Ft Trumbull Conn and report for temporary duty during the absence on leave of Capt H P Birmingham, Asst Surgeon

Major Washington Matthews, Surgeon, having been found incapacitated for active service by an Army retiring board, on account of disability incident to the service, is by direction of the President retired from active service this date, Sept 26 1895

Capt Thomas U Raymond Asst Surgeon, is granted leave of absence for four months, to take effect about Nov 5, 1895

PROMOTION

Capt Louis W Crampton, Asst Surgeon, promoted to be Surgeon with the rank of Major Sept 6 1895

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending October 5 1895

Medical Director E S Bogert, detached from duty in charge of naval hospital at New York, November 1, and ordered to attendance on officers of the Navy in that city

Medical Inspector T N Penrose, ordered to duty November 1 in charge of the naval hospital at New York, in addition to his present duties

Surgeon R C Person's recent orders are so far modified that, when detached from the "Minnesota," he is ordered to special duty in connection with the improvements of the naval hospital at New York

Surgeon L G Heneberger, ordered to duty in attendance on naval officers in New York

Marine-Hospital Changes Official list of changes of station and duties of Medical Officers of the U S Marine Hospital Service, for the fifteen days ended September 30 1895

Surgeon C S D Fessenden, granted leave of absence for thirty days, Sept 24, 1895

Surgeon P H Bailhache detailed to represent Service at meeting of American Public Health Association, Sept 24, 1895

Surgeon J M Gassaway granted leave of absence for one day, Sept 21, 1895, and for fifteen days, Sept 28, 1895

Surgeon H R Carter, granted leave of absence for one day, Sept 24, 1895

P A Surgeon S D Brooks, directed to proceed from Chicago, Ill , to St. Louis Mo for temporary duty, Sept 16, 1895

P A Surgeon L L Williams, relieved from temporary duty at South Atlantic Quarantine and directed to rejoin station at Charleston, S C Sept 19, 1895 Granted leave of absence for twelve days Sept 25 1895

P A Surgeon J J Kinyoun detailed to represent Service at meeting of American Public Health Association, Sept 24, 1895

P A Surgeon J B Stoner, granted leave of absence for thirty days, Sept 20, 1895

P A Surgeon M J Rosenau, to proceed from Eagle Pass, Texas, to San Francisco Quarantine Station, for temporary duty Sept 16, 1895

Asst Surgeon L E Cofer granted leave of absence for thirty days, Sept 28 1895

Asst Surgeon J A Nydegger, to proceed from Savannah, Ga to Mobile, Ala for temporary duty, Sept 16, 1895

Asst Surgeon J H Oakley, granted leave of absence for thirty days Sept 30, 1895

Vol XXV CHICAGO, OCTOBER 19, 1895 No 16

ADDRESS

STRENGTH OF THE DIFFERENT MYDRIATICS AND MYOTICS

CHAIRMAN'S ADDRESS

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md., May 7-10 1895

BY EDWARD JACKSON A M , M D
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC
SURGEON TO WILLS EYE HOSPITAL, PHILADELPHIA

It will naturally occur to you that the development of our own Section work, the increase in the number of papers presented here which raise points for our discussion, and the increase in the number of members who can from their own observations add to the value of our discussions, together with the multiplication of ophthalmic journals, has rendered obsolete the Address which the By-laws of the American Medical Association say the Chairman shall prepare "on the recent advancements in the branches belonging to his Section " My predecessors for some years seem to have felt this and have chiefly confined their remarks to the other topic allotted them, viz , "suggestions in regard to improvements in methods of work "

Such suggestions as I would make regarding the conduct of our Section have been embodied in the arrangement of our program, or will appear in the course of our proceedings The most important of them is in the attempt to enforce brevity in the communications that are to be read before us In this effort I ask your assistance—that as readers of papers or speakers in discussion you will not ask for extension of time—and that as members of the Section you will bear in mind the rights of those who have not yet obtained the floor, as against the natural desire of a speaker to communicate more than a fair share of his ideas

For a gathering such as this, the elementary principles, the complete and rounded treatise, the historical review, the miscellaneous details of cases, even the professional experiences of the speaker, except as they bear directly on the point under discussion, are all out of place The office of the written paper here is to awaken and shape the discussion If you have new facts, even of the highest importance, that will awaken no criticism from our experience, suggest no questions that we want to put to you, do not bring them here You can communicate them more cheaply and more perfectly through the printed page The medical society should not be a contrivance for stuffing unwilling victims with even the most valuable information If we have tried to use it for that purpose, let us stop doing so

It may often happen that with the papers that are to be printed, as well as read here, we may desire that as they appear in the Journal, or our volume of Transactions, they should contain matter not essential to the intelligent consideration of the points raised for discussion Such matter may well be included in the paper, but omitted in the reading

The absurdity of addressing you on current ophthalmic literature, with the chief additions to which you are already familiar, is too apparent to demand any apology for turning quite aside from such a course I have chosen, therefore, to speak chiefly on a particular topic, important in itself, but I think especially appropriate, because complete knowledge of it will be best reached through collective investigation

RELATIVE STRENGTH OF MYDRIATICS AND MYOTICS

With the first medical use of any drug there arises the question of dosage, so that views, more or less positive, are current with reference to the absolute and relative strength of our various mydriatics and myotics They are, however, little more than indefinite impressions, such as would not be tolerated among the accumulations of an exact science like chemistry or physics, and it is, I believe, quite within our power to replace them by definite knowledge The mutual antagonism of these two classes of drugs, and the readiness and exactness with which we can measure the diameter of the pupil and the distance of the near point of accommodation, render this the field in which we can first gain exact quantitative knowledge of the physiologic action of drugs In other investigations of the kind, we may know exactly the dose applied and the body weight of the animal to which it is applied, but have commonly, no means of exactly measuring for comparison the result produced In this matter of the dilatation or contraction of the pupil, the increased or diminished effort of the ciliary muscle, cause and effect, factors and product, can both be estimated with exactness

The effect of a mydriatic on the eye can be most accurately observed subjectively, the subject of experiment making the observation, and one eye only should be subjected to the influence of the drug at one time, the other being kept normal for control of illumination and for comparison, the size of the pupil is to be measured by the distance apart of pinhole openings that give tangent circles of diffusion on the retina I have employed a series of pin holes punched in a piece of cardboard, the distance between them varying by ¼ millimeter intervals from 2 mm. to 9 mm The effect on accommodation is tested by placing a lens before the eye subjected to the drug, convex for a mydriatic, concave for a myotic, and covering first one eye, then the other, while they are both made to focus fine print at the near point of distinct vision, and changing the lens used until that strength is found which most accurately neutralizes the influence of the drug on the ciliary muscles Complete absence of accommodative power or pupillary reaction is ascertained by the ordinary methods

In the experiments now referred to, I have used the various drugs dissolved in distilled water, in proportions varying from 1 to 10 (homatropin) to 1 to 2000000 (hyoscyamin, etc) and have applied them by dropping on the cornea with a pipette, giving 180 drops of water to a drachm

As the measure of the strength of a mydriatic we may take the amount required to produce either of several definite physiologic effects Thus we may take the strength of the solution when carefully applied that will constantly produce the least effect that can be certainly recognized This I have found to be for pilocarpin (hydrochlorate), 1 2000, or 1-6000 gr , homatropin (hydrochlorate), 1 10000, or 1-30000 gr , eserin (sulphate), 1 50000, or 1-150000 gr , atropin (sulphate), 1 500000, or 1-15000000 gr , hyoscyamin (hydrochlorate), 1 1000000, or 1-3000000 of a grain

What will be said of the strength of hyoscyamin applies equally to duboisin and scopolamin, and probably to daturin In the Transactions of the Medical Society of the State of Pennsylvania for 1882, p 157, I published a study of the subject, and the conclusion reached through it that, "Daturia, duboisia, and hyoscyamia are physiologically identical" Recently I have carefully compared the actions of duboisin and hyoscyamin with that of the newly introduced scopolamin, and have not been able to discover any difference between them

This relation of the sizes of the minimum dose is a simple one, easily ascertained, and one that each of you may verify or correct without causing yourselves any personal inconvenience It is to be hoped many will test it, as its general study would almost certainly reveal important facts as to susceptibility and idiosyncrasy

But in practice we use these drugs in doses enormously greater, and when so used the ratios of their strengths differ markedly from those above indicated In general it appears that those drugs whose action is more evanescent, require to be used in relatively larger dose to produce the minimum effect, that is, in practical doses they prove relatively stronger This will appear on comparison of the foregoing with the data to be given presently

A more practical measure of strength is to be found in the amount of the drug required to produce full dilatation of the pupil or complete paralysis of the accommodation For purposes of comparison, however, a method which eliminates errors from imperfect instillation and absorption of the drug is to determine the strength of the different mydriatics by observing their power to neutralize a rather strong (1 to 1000, nearly 5 grain to the fluid ounce) solution of eserin sulphate

The trial has been made by using a single solution containing both the drugs in the desired proportions When this is resorted to, the myotic effect is first manifest, and as it declines the mydriatic becomes predominant This is the case to a slight extent even with homatropin, and is much more marked with the slower mydriatics, especially atropin Still, even with atropin, there is a time at the beginning of its maximum effect when the influence of the eserin has scarcely begun to decline, when they can be made to closely neutralize each other

Taking this period of most complete neutralization, which is about one and one-half hours after instillation for homatropin, two and one-half hours for hyoscyamin, and three and one-half hours for atropin, I find that to neutralize the influence of the mydriatics requires for 1 part homatropin, 1-6 part eserin, 1 part atropin, 5 parts of eserin, 1 part hyoscyamin, 12½ parts eserin, 1 part homatropin, 4 parts pilocarpin

Taking homatropin as the unit, the relative strength of the mydriatics and myotics then appears to be pilocarpin (hydrochlorate), ¼, homatropin (hydrochlorate), 1, eserin (sulphate), 6, atropin (sulphate), 30, hyoscyamin (hydrochlorate), 75

These proportions hold pretty nearly for either the effects on the pupil or on the accommodation, although in my own eyes (the only ones in which I have been able to note very accurately the changes in the accommodation), the mydriatics have all shown a relatively greater effect on accommodation That is, in the transition from myosis to mydriasis, there has in each instance been a time when the pupil still remained contracted, although the accommodation had descended below the normal

The strengths of the mydriatics and myotics that I have thus indicated has been ascertained by experiments first on my own eyes Nearly all have been confirmed by experiments on the eyes of other persons, but not any large proportion of them on the eyes of any one person In many respects these observations agree with the recorded observations of others, as with Risley, in his conclusion published in his first account of duboisin, that its influence on the accommodation was more than twice as great as that of atropin, and the chief results obtained by Donders and von Graefe and their students experimenting on atropin and extract of calabar bean

But in some respects the published conclusions of earlier observers have not been confirmed This has been especially the case in regard to minimum doses Thus Loring, for atropin, found the minimum strength that would produce a notable effect on the pupil to be 1 150000, and Jaarsma (quoted by Landolt) concluded that a drop of either of the following solutions was the minimum dose that would affect the pupil pilocarpin, 1 400, eserin, 1 12800; atropin, 1 80000, daturin, 1 160000, duboisin, 1 1200000 He thought that it required a strength of 1 800 of eserin to affect the accommodation Graefe speaks of the dilatation produced by a solution of 1 120000 of atropin "long kept in contact" with the eye of a dog The weakest solution of atropin referred to by Donders in his work was 1 14400, of which he says "On the following day no trace of mydriasis is perceptible" ("Accommodation and Refraction of the Eye," p 588) I have, after the instillation of one-third of a minim of a 1 500000 solution of atropin containing 1-1500000 of a grain of the drug, found a mydriasis amounting to 25 of a mm , greater diameter of the pupil, after twenty-four hours Subsequently, however, Donders became better acquainted with the mydriatic power of atropin, as is shown by the following letter published in the "Life and Letters of Charles Darwin," vol ii, p 498

Down, July 7, 1874

My dear Professor Donders —My son George writes to me that he has seen you and that you have been very kind to him, for which I return to you my cordial thanks He tells me, on your authority, of a fact that interests me in the highest degree, and which I much wish to be allowed to quote It relates to the action of 1-1000000 of a grain of atropin on the eye Now, will you be so kind, whenever you can find a little leisure, as to tell me whether you yourself have observed this fact, or believe it on good authority? I also wish to know what proportion by weight, the atropin bore to the water solution, and how much of the solution was applied to the eye? The reason why I am so anxious on this head is, that it gives some support to certain facts repeatedly observed by me, with respect to the action of phosphate of ammonia on Drosera The 1 4000000 of a grain absorbed by a gland clearly makes the tentacle which bears this gland become inflected , and I am firmly convinced that the 1 20000000 of a grain of crystallized salt (i e , containing about one-third of its weight of water of crystallization) does the same Now I am quite unhappy at the thought of having to publish such a statement It will be of great value *to me to be able to give any analogous facts in support* The case of Drosera is all the more interesting as the absorption of the salt or any other stimulant applied to the gland causes *it to transmit a motor influence to* the base of the tentacle which bears the gland

Pray forgive me for troubling you, and do not trouble yourself to answer this until your health is fully reëstablished Pray believe me, yours very sincerely,

CHARLES DARWIN

The fact here asked for is used in Darwin's "Insectivorous Plants," chap VII It is the dilatation of the pupil of the dog by 1-1000000 grain of atropin applied directly to the iris But I have read this letter, not merely because it supports my observation as to the mydriatic power of atropin, but because in it lies revealed a general fact most worthy of our consideration Does it appear to any of you that here are two great men in their dotage, pleased with mere trifles? You have then but poorly traced the course of scientific progress This letter indicates the importance attached by two of the greatest scientists of our century to exactness and definiteness of observation , and all the history of scientific progress testifies that they were right in their estimate

The observation of the Greek philosopher in his bath tub, of the loss of weight by displacement of water, with a few similar observations furnished a foundation on which physics grew up, centuries before her sister sciences were imagined For a thousand years the alchemists distilled and compounded and theorized, until in the eighteenth century, Black took to carefully weighing the products of his experiments Priestley and Cavendish, Scheele and Lavoisier followed him, and in a single generation the crude theories of alchemy dissipated as mists before the morning sun, revealing the great vistas of modern chemistry Within the year we have witnessed the proclaiming of a new element in our atmosphere, revealed simply by the minute difference between the weight of supposed nitrogen procured from the air, and nitrogen procured from other sources

We all look forward to a day when we can speak with more truth of a science of medicine Let us remember that it will come, and only come, as we bring the balance and the rule, and all other means of minute exactness into our methods of clinical investigation

THE KRAG JORGENSEN RIFLE

A REPORT OF ITS EFFECTS ON THE SKULL OF THE LIVING, SHOWING THE FALLACY OF THE "HUMANE" THEORY ON GUNSHOT WOUNDS FROM THE MODERN RIFLE

BY MAJOR ALFRED C GIRARD, SURGEON U S ARMY
FORT SHERIDAN ILL

The shooting through the head of a military convict attempting to escape from a sentinel at this post, with the Krag-Jorgenson, the new rifle adopted for the United States Army—presenting the first instance *in the country of its effects* on the skull of the living subject, *has led to various sensational accounts in the* secular press Based on these, I have received a number of letters of inquiry from physicians interested in the result of the change of caliber In order to prevent erroneous deductions from newspaper reports, and to give the profession a true description of the *injury produced, I have deemed proper to publish* this account, with a sketch of the skull as it appeared after removal of the integument

I saw the man a few minutes after he was shot His breathing was stertorous , he was, unconscious, and death appeared to be only a question of minutes A cursory examination revealed two bullet wounds The entrance wound (he was running away when shot), was located in the upper occipital region of the skull, and that of exit in the forehead a little to the right of the center (Distance between rifle and victim ninety feet) After passing through the man's skull, the ball went through a tree eight inches in diameter and buried *itself in* the ground two feet The man died in half anhour

Post-mortem was made the same night The wound of entrance into the skin presented a round opening, without the appearance of scorching or blackening The wound of exit in front was larger and more ragged The integument was carefully dissected off and the bone of the top of the skull found extensively fractured, the parts being connected here and there by fascia

On the calvarium being removed, the surface of the dura mater presented a state of intense congestion To the right of the longitudinal fissure it was torn through for a distance of about four inches, about one inch from and parallel to it

On removal of the coverings, the convolutions of the brain were made prominent by the engorged network of superficial veins A furrow, corresponding to the injury of the dura was ploughed through the right hemisphere, in the region of the superior frontal convolution, about half an inch deep The right lateral sinus appeared filled with blood serum , the left was normal On section, the vessels of the brain were found engorged, but no other macroscopic injury of a prominent nature was apparent

After removal of the brain, the cribriform plate exhibited comminuted fracture , one or two slight fissures in the petrous and squamous portion of the temporal bone, otherwise the bone was intact

The skull cap presented the following injuries, viz at the site of the entrance of the bullet, one half inch above and to the right of the junction of the occipital and right parietal bones, an oval perforation 1 x ½ inch, the edges shelving inward From this opening there radiated the following fractures, viz

1 Downward into the left lambdoid suture, separating it, thence horizontally along the parietal and frontal bones to the left orbital cavity

2 An oblique into the sagittal suture, opening it *for two inches*

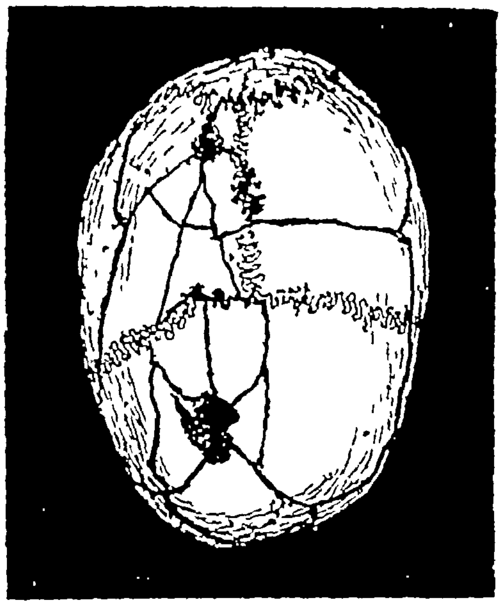
3 One parallel with the sagittal suture, bifurcating one inch from its origin into a wedge-shaped piece, which, again fractured, continued to the coronal suture separating it

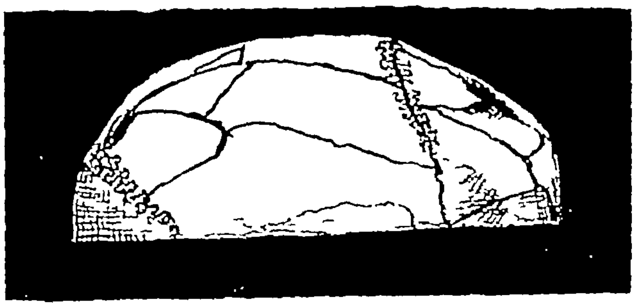
4 The left fracture communicated with the horizontal left fracture, described under 1, parallel to the coronal suture and one and a half inches to the rear

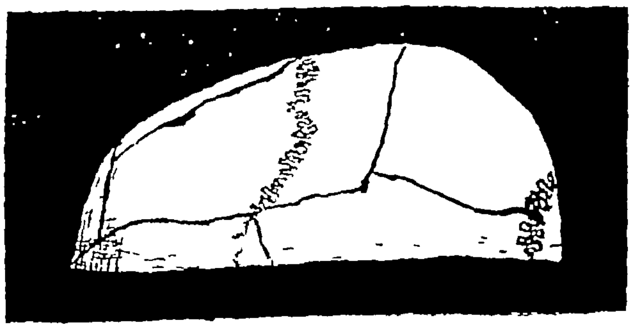
5 A fracture at an acute angle from the former to

the right, communicating with the former, and with the lambdoid, two inches to the right of the superior angle of the occipital bone, and toward the front, extending into the coronal suture

The wound of exit, two inches in front of the coronal suture and one inch to the right of the median line, was pyriform, one and a half inches long at its greatest diameter, three-eighths of an inch wide, the edges more ragged It communicated with the coronal suture by three fractures, with the orbital ridge by two, and thence with the horizontal breaks







A C Girard, del

Death was evidently caused by concussion, as no vital parts of the brain were injured, and the hemorrhage was not considerable

Now as to the effect of the bullet, the so called humane result of this small caliber bullet, not much larger than a pencil, may be disposed ot at once in the negative The bullet was recovered and showed but a slight indentation,—the openings, considering the pulverization of bone in the immediate vicinity of the impact were small We had clearly, what is called an explosive effect

A few words of explanation on the *modus operandi* of such an injury are necessary to lead to a correct understanding Theories, such as the effect of powder gases, heating of the bullet, have generally been abandoned There was no deformation of the bullet or lateral impact, which might increase the striking surface

I would exceed the limits, which have to be given to an article of this nature, if I attempted to give even in a condensed manner the experiments, which have led to the present views on this enormously destructive result accompanying an apparent slight bone defect The conclusions arrived at have to be sufficient, and any one taking a special interest in the matter will find a complete history of the experiments in the *Bibliotheca Medica*, edited by Kocher, Konig and Mikulicz, names which guarantee the correctness and soundness of the accounts given (Part E, 2, 1895)

Modern projectiles act in a twofold manner first in the line of the impact, and second, in a lateral direction In both cases we observe beside the immediate effect, motion, which is communicated from the place of impact If the result of impact leads to perforation, then the lateral effect is lessened in corresponding ratio It depends on the cohesion of the molecules, on the diameter of the projectile, and on its velocity In common terms it may be stated that the greater the cohesion, the more energy is wasted and the lesser the lateral effect—the greater the diameter, the more force is lost in the impact, but the greater the velocity, the more extended the lateral transmission of motion as the molecules have not the time to escape the lateral compression and communicate their motion until a place of minor resistance is reached, when disruption follows This is the so-called explosive effect, which more properly should be called expansive This is illustrated in our case by the penetration of a small bullet at a high velocity The defect at the place of impact is small, but the lateral motion was such that the skull was raised from its base by the horizontal fractures and as this did apparently not suffice to limit the motion, the upper fragments were torn from their fascial connection

In addition to this direct expansive effect on the bone of the skull, there is the hydrostatic result of rapid compression of the semi-fluid brain mass, confined in it The molecules of liquids are readily displaced and a greater effect will be produced in them by a relatively smaller velocity, and with high velocity it is enormous

It must be understood that the small caliber has not *introduced* the explosive effect, but owing to the higher velocity and consequently greater impact with a lesser diameter, it has *extended the zone* of explosive effect, always observed in large caliber projectiles, as long as they are moving under high velocity

We may therefore give the following resumé of this case a direct impact under the highest kind of velocity, without deformation of the bullet, small hole of entrance and exit of the bone, with extended stellate and circumferential fracture of the skull, partly due to direct impact, partly to lateral expansive motion, and partly to the hydrostatic effect of compression of the semi fluid brain by the bullet, with displacement of the molecules in all directions, and disruption at the place of least resistance

The base of the skull was not affected by the hydrostatic pressure because the dome was already weakened by the expansive effect of the direct impact, as shown by the longitudinal fractures and their branches

Since completing the above, it has occurred to me that readers who are not familiar with the later experiments in gunshot injuries, might not readily understand what the "humane" theory is, and I therefore add a few words of explanation

When the first experiments with the small caliber gun were made, it was found that occasionally the epiphysis of a bone showed an almost clean perforation and the rash conclusion was drawn that the new class of weapons, instead of shattering the bones and tearing the flesh, would make almost a punctured wound, therein they would be more humane

The main fallacy in these experiments was that they were made on dry bones, in which the cancellated tissue of the epiphysis readily gave way to the lateral effect and thus the explosive result did not occur In all experiments on fresh bones, and on bony cavities filled with a pulp resembling brain matter, the explosive action was manifest, as it has been found in the practical exhibit of the case under consideration

INCIPIENT CATARACT

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10 1895

BY ALBERT RUFUS BAKER, M D

PROFESSOR OF OPHTHALMOLOGY, OTOLOGY AND LARYNGOLOGY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF WOOSTER
CLEVELAND OHIO

It is surprising how little real progress has been made in our knowledge of the etiology and pathology of cataract since the investigations of Marriotte,[1] Boerhaave[2] and Brisseau,[3] two hundred years ago

In a paper read before this Section in 1892, I presented some thoughts on infantile cataract[4] What I have to say to day will apply more particularly to the so called senile and other forms of cataract in adults

In a large manufacturing city, like Cleveland, nearly one-half of the opacities of the lens coming under the observation of the ophthalmic surgeon are the result of traumatism, but as a discussion of injuries of the eye would require more than ten minutes, I pass to the consideration of other forms of cataract

That there is a diabetic cataract is now generally recognized That under dietetic and medicinal treatment the opacity of the lenses may disappear is not so generally conceded, although cases have been reported by Seegen,[5] Tannahill,[6] Nettleship[7] and others

In a paper[8] read before the Ohio State Medical Society in 1889, I reported the case of Mrs S, aged 43, first seen in April, 1884, cataract almost mature, could not count fingers with either eye Urine contained large amount of sugar which almost entirely disappeared under dietetic and medicinal treatment Vision rapidly improved to O D, 20-70, O S, 20-60 Continued to see very well with occasional fluctuations in vision according to amount of sugar in urine, until September, 1888, a period of four and one half years, when after exposure she had suppression of urine and died suddenly in coma

Since reporting the above case, Mr M came under my observation Aged 56, having diabetic cataracts in both eyes Left lens extracted in October, 1888 Shortly afterward he went abroad, lived much of the time at Carlsbad, drinking plenty of water and living on restricted diet In February, 1894, he returned to this country improved in health and much to my surprise had discarded the cataract lenses and was using the unoperated eye with presbyopic lens

Notwithstanding the general statement of recent writers to the contrary (Schmidt Rimpler)[9] I believe that further observation will show that there is a nephritic as well as a diabetic cataract Eight out of thirty consecutive cases of cataract, in one hospital in my service, had albumin in the urine, although kidney disease was not suspected by the patients or family physicians Deutschman[10] recognizes this not as a coincidence but says "We must recognize a nephritic cataract just as we recognize a diabetic cataract, the cause in both cases being constitutional" Becker in the *Verhandl d Heidelb Ophth Vers* 1884, denied Deutschman's statement that chronic nephritis leads to cataract

The only case in which I have observed any marked improvement in vision in a nephritic cataract was that of Mr O, aged 62, mature cataract of right eye, immature cataract of left, vision S 20-200, operation of linear extraction performed on right eye in October, 1883, vision after operation 20-30 Urine contained a large amount of albumin and casts There was a slight hypertrophy of the heart, but no valvular disease Dietetic and medicinal treatment for the albuminuria was instituted with quite satisfactory results At the end of a year found that his vision had improved to 20-50, S, in the unoperated eye, and that he had discarded the cataract spectacles and was using his old ones, with which he claimed to see better He continued to use a pair of +2 50 D lenses for five years, when his sight began to fail rapidly in left eye and he returned to the use of the cataract lenses About the same time, there was a decided increase in the amount of albumin in the urine, the old gentleman after suffering from edema of the feet and legs and other serious results of kidney disease, died in 1891

Numerous cases of cataract as the result of ergotism have been reported Rickets is not infrequently said to be a cause of cataract as well as a certain form of skin disease Glass blowers' cataract is recognized, and I have found cataract quite frequent among puddlers and other employes about iron mills who are exposed to intense heat

Fraenkel,[11] of Lyons, "believes that cataracts are due to disorders of nutrition, i e, that they are due to auto-intoxication" Of thirty-four cases he reports, in thirty three the urine contained less than the normal amount of toxic substances

Collins[12] believes that the cataract process is not an exaggerated senile change but due to disturbed nutrition of another nature, in so far as chemic and morphologic changes are concerned

Roosa[13] reports a case of cataract following a stroke of lightning which subsequently almost entirely disappeared

Risley[14] says "That while opacity of the lens is a disease of advanced life, it does not in all probability depend upon senile changes, but is originated in local pathologic states involving the nutrition of the eye itself" These local pathologic changes he believes to be in the choroid, and thinks the changes in the lens and vitreous in later life to be due to the same cause as the impaired nutrition of the sclera and the resulting posterior staphyloma and consequent myopia in children He attributes the comparative freedom from cataract in early life to the yielding of the sclera, which prevents the lens from suffering from injurious disturbances of nutrition In support of this theory of the cause of cataract Dr Risley presents statistics of sixty cases taken consecutively from his case book, in forty of which there was a choroiditis noted, and in many of the other twenty the opacity of the lens was so far advanced as to prevent a study of the fundus oculi

I can recall five or six cases in which a preliminary iridectomy has been performed, and the patients have waited from one to fifteen years for the cataract to become ripe, at the present time they are no nearer maturity, and in two or three cases the lens is clearer than at the time of the iridectomy

Thomas[15] and White[16] each report a case in which after triturating the lens to hasten maturity, the opacity disappeared entirely

Witvalsky[18] has collected eighteen cases of spontaneous cure of senile cataract by absorption, reported within the past eight years, to which he adds two of his own and concludes that such cases are much more common than is generally supposed

High degree of myopia has long been recognized as a predisposing cause of cataract—the same is true of glaucoma, the one can often be prevented by spectacles and the other cured by operation While it is true that these are exceptional cases that we all recognize and act upon, is it not true that more of the cases of cataract if recognized earlier and studied carefully might be retarded or even cured? So many "cures" for cataract have been proposed by ignorant and unprincipled practitioners that any one proposing to treat incipient cataract is generally looked upon either as a fool or a knave Consequently we have generally been contented to give the advice "Wait until the cataract becomes ripe," and have not given these cases that honest study and close observation that we have many other diseases

I do not believe that clinical observation will confirm Priestly Smith's[17] conclusions in all cases, "that senile cataract is entirely a local process and is not dependent on any disordered state of the general health"

In view of the preceding observations, may we not say that occasionally incipient cataracts under medical, hygienic, dietetic or local treatment do remain stationary or even entirely disappear and that the resources of our art looking toward this end have not been entirely exhausted?

In conclusion, I wish to suggest that in all cases of incipient cataract 1, the urine should be examined chemically and microscopically, 2, the general health should be carefully interrogated, 3, all errors of refraction should be corrected, 4, a careful examination of the fundus oculi should be made, 5, that the patient receive such general and local treatment as may be suggested by the above inquiries, 6, that a few carefully reported histories of cases from incipiency to maturity would be of more value than statistics of hundreds of successful operations, 7, that if operative interference becomes necessary it should be instituted at the earliest possible moment before the general health becomes impaired, preferably by Knapp's[10] method of peripheral capsulotomy, with an iridectomy either at the time of the operation or some time previously

THE OPERATIVE TREATMENT OF IMMATURE AND SOME FORMS OF ZONULAR CATARACT

Read in the Section on Ophthalmology, at the Forty sixth Annual Meeting of the American Medical Association, held at Baltimore Md May 7 10, 1895

BY JOHN E WEEKS, M D

SURGEON NEW YORK EYE AND EAR INFIRMARY, PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY
NEW YORK

In the formation of ordinary senile cataract, the shrinkage of the nuclear portion of the lens, as has been pointed out by Becker, plays an important part The shrinkage of the peripheral lamellæ does not progress as rapidly as those of the nuclear portion, and, as a result, a process of cleavage between peripheral and nuclear lamellæ is set up The spaces thus formed are occupied by an emulsion known as the liquor Morgagni, which is composed of granular detritus, fat globules, myeline masses, and the intraocular fluids, and serves to produce the whitish opacities observed The peripheral fibers themselves usually undergo degenerative changes—become filled with minute fat globules, break up into myeline masses and are sometimes entirely disintegrated. The liquor Morgagni forms between the capsule and the lens fibers, as well as between the lamellæ, serving to render the attachment between the two less intimate At the earlier moment of this occurrence, the cataract is at the best stage for removal, however, this process is not gone through with in many cases of nuclear cataract

In the rapidly developing cataract, particularly in relatively young individuals, the lens fibers become swollen by the imbibition of fluids and the granular degeneration of the fibers progresses very rapidly. The white soft cataract is the extreme example of this process In these cases a stage of swelling is marked and the anterior chamber is rendered quite shallow When the lens fibers are swollen, although they may be quite opaque, they are not readily detached from the capsule The stage of shrinkage which follows, after it has proceeded sufficiently to permit of the presence of an anterior chamber of moderate depth, is more favorable for complete removal of the cortical portion, as some liquor Morgagni has been formed between capsule and lens In many cases of cataract, where the process of cleavage plays a decided rôle, the stage of swelling does not develop The nuclear lamellæ remain transparent, often are amber-hued, or show very little change, and the peripheral fibers degenerate very slowly In still another form, occurring in older individuals, the opacity begins in the central portion of the lens, in the form of a diffuse haziness and advances slowly toward the periphery In this form a stage of swelling seldom occurs, the lens being always smaller than the non-cataractous lens of the same age In still another form the lens takes on a deep amber hue, all the fibers are hardened and condensed and there is marked haziness of the nuclear portion In the last class of cases no liquor Morgagni forms, however, the sclerosed lens is quite easily detachable from the capsule In the forms of rapid development the vision is much reduced at an early stage In some cases in which the cleavage affects the equatorial portion or the posterior cortex of the lens, vision becomes reduced, but often remains fairly good for a number of years In many cases of nuclear opacification and in the typical sclerosed lens, the vision may become reduced to 20–100 or less and remain at that point for a long period of time In the class of cases last mentioned, the patient reads with difficulty, if he reads at all, and the degree of vision is not sufficient to permit him to perform the ordinary duties of life

There are also cases of lamellar cataract in which the opaque zone is large and dense, in some, calcareous deposits have taken place In the process of the development of all forms of cataract there is a stage between the loss of useful vision and the formation of a condition which renders the detachment of the lens fibers from the capsule most easy, which may extend over a few months or a few years This stage is most distressing to the individual and in not a few instances entails hardships on the patient or the patient's family

During a long experience in the removal of the non-cataractous lens, at the dead house, conducted for self-instruction, as well as for the instruction of students in the operative surgery of the eye, the writer has studied the behavior of the cortex of the transparent lens It was observed that in the lenses that were twenty-five or thirty years old, the nuclear portion was fairly firm, about two thirds of the mass of the lens coming away with the nucleus It was further observed that much of the detached cortex could be made to follow the nuclear portion The firm nuclear portion became larger as the age of the lens increased On the strength of these observations, in spite of the dictum "hands off" in reference to operations on immature cataract, the writer began to remove the cataractous lens, soon after it had reached a degree of opaqueness sufficient to interfere with useful vision, whatever the form of the cataract might be Before this plan was followed, the operation of ripening, advocated by Forster was tried in a number of cases, two of which are given in the following table The lenses became rapidly opaque, but it was found that removal six weeks or two years later, was complicated by adhesion of cortical substance to the capsule, to probably the same extent as would have occurred had the extraction been performed at the time of the Förster operation This experience was sufficient to cause the writer to abandon all ripening operations as not of sufficient value to compensate for the extra liability to accident and to inflammatory changes consequent on them The writer now extracts at once when the opacity, whether posterior, cortical, nuclear, or peripheral or of any other form, interferes sufficiently with vision to render it of little value to the individual If the lens is much swollen, the operation is postponed, and if the individual can wait until shrinkage occurs, without great sacrifice If he can not, extraction is performed

The form of operation attempted in all uncomplicated cases is—simple extraction, making the incision in the limbus and including about two fifths of the circumference of the cornea, in individuals of 45 years or upward; and a little less in younger individuals The incision is made large enough to permit of the easy extrusion of the firm nuclear portion of the lens As much of the cortical substance as possible is removed by stroking upward over the cornea with spoon or lids, or by means of Critchet's or de Wecker's spoon passed into the anterior chamber Lavage is seldom practiced If, during the operation, any indication for the performance of iridectomy arises, iridectomy is performed It has been found that in the large majority of the cases, iridectomy may be avoided

Does the cortical substance that may remain in the eye after the extraction of immature cataract give rise to inflammatory trouble? The writer has never seen it Substances capable of producing irritation, such as tabular crystals of cholesterin or minute deposits of lime, do not exist in the cortex of the immature cataractous lens, but do appear in greater or less quantities in the cortex of the hyper-mature cataract and their escape from the lens capsule is not infrequently accompanied or followed by irritation to the eye, of greater or less severity The cortex of the immature cataract absorbs slowly if it lies in a capsule which has been opened near its periphery and in which the opening is small If the capsule has been opened freely, which I endeavor to do, absorption of the cortical substance advances rapidly

The accompanying table gives the results of operation in twenty five cases in which an immature condition of the lens was present

The twenty-five cases reported were divided as follows

Immature soft cataract, three cases Two occurred in the same individual and were due to extreme prostration from sea-sickness, during an ocean voyage Forster's operation was performed before the extractions were attempted At the time of the extractions, which followed three weeks after the Forster operation in one case and two years after in the second case, the cortical substance was still quite adherent to the capsule in both Vision of 20–70 was eventually obtained in each eye The third occurred after gummatous iritis, during the process of which a broad posterior synechia formed, only part of the lens was opaque About one-half of the lens substance remained in the capsule In three months the cortex was entirely absorbed and vision of 20–20 + was obtained

Zonular cataract, five cases The ages of the patients were, 19 years, two, 20 years, one, 49 years, two In two of the cases the nucleus was dense In two cases, chalky deposits were present in the opaque zone Mild iritis developed in one of the latter cases In all cases some cortical lens matter remained in the capsule after the first operation The immediate vision was 20–40, two, 20–100, one, 18–100, one, 1–8, one The ultimate vision was 20–20 +, two, 20–30, one, 20–40, one All were simple extractions except one

Immature complicated cataract, four cases Two cases occurred as a result of heredito specific kerato-iritis and were of the diffuse variety, these were removed by the combined method (with iridectomy) The lenses which were mummified came away entire Ultimate vision 20–70 in each eye This could not be improved because of numerous macular opacities of the cornea One case was complicated by adherent leucoma due to corneal ulcer, occurring in the lower third of the cornea Iridectomy—vision of

23	M	51	Alcoholic	Immature Senile	Good V = 12 200	March *11, '95*	Cocain 4 per cent *simple, some lens cortex remained*	Uneventful	12	20-40	Apr 9, '95	20-15	Lens cortex completely absorbed
24	M	42	Good	Immature Senile Nuclear	Good V = 18 200	March 19 '95	Cocain 4 per cent simple, some lens cortex remained	Uneventful	17	20-40	Apr 23, '95	20-20+	Lens cortex absorbed
25	M	42	Good	Immature Senile, Nuclear	Good 20 100	March 26, '95	*Cocain 4 per cent* simple	Uneventful	17	20-50	Apr 27 '95	20-20+	

20–70 was obtained One case was that of an immature traumatic cataract following a blow on the eye A simple extraction was performed Vision of 20–40 was obtained Posterior cortical cataract, one case Simple extraction was performed But very little difficulty was experienced in freeing the eye of the greater portion of the cortical substance Vision of 20–20 was obtained

Immature diabetic cataract, one case The extraction, after the simple method, was not accompanied with difficulties Vision of 20–20 + was obtained

There were twelve cases of ordinary senile cataract, four of which were of the diffuse nuclear variety which develops very slowly Simple extraction was performed in all and was not accompanied with unusual difficulty Some cortical substance remained in almost all cases, but was absorbed almost if not entirely in a few weeks, giving no trouble *No* iritis occurred in these cases Prolapse occurred in one case only and was probably due to traumatism The healing in these cases was uneventful and the vision eventually obtained was extremely satisfactory The immediate vision was 20–20— two, 20–30, one, 20–40, three, 20–50, six, 16–200, one, 4–200, one

The ultimate vision after discission in twelve cases 20–15, one, 20–20+, six, 20–20, two, 20–30, one, 20–40, one, 20–50, two

In the twenty five cases there were no losses Iridectomy was done in six cases Simple extraction in nineteen cases One prolapse occurred Discission was done in twenty cases

The ultimate visual results were as follows 20–20 or better, thirteen, 20–30, two, 20–40, three, 20–50, two, 20–70, five The youngest patient operated upon was 17 years, the oldest, 75 years The mean, 45¼ years In all cases the remaining cortex absorbed almost, if not entirely, either before or after discission was performed

The results appear to the writer to be as favorable as those obtained by the removal of cataract ordinarily, at the stage of maturity, and the relief to the patient was in many cases very great, saving them one, two, or even more years of idle waiting

The difficulty of removing immature cataract is greater than that of removing mature cataract and should be done by expert operators In the hands of expert operators the danger is little more than where the lens is ripe

154 Madison Avenue

DISCUSSION ON PAPERS OF DRS BAKER AND WEEKS

Dr George E Frothingham, Detroit Mich —In regard to the paper of Dr Baker I will say that I agree in the main with the views of the author While I *think it* is the experience of most of us that any considerable opacity of the lens never fully clears up, slight opacities may nearly disappear, and we find commencing cataract at times due to change of nutrition of the lens, dependent upon disease *of the* choroid or some constitutional disease, that may be relieved and with the effect to retard or arrest the development of the cataract I remember one case in my *practice in which the* development of a cataract evidently due to choroiditis has apparently been arrested, at any rate it has made no progress for about *seven years* With the conclusions in Dr Baker's paper, I fully agree They are in accordance with the general principles that in incipient cataract we should make a careful and thorough examination *of* the eye and of the general condition of the patient and remedy any pathologic conditions so far as we can

In regard to the paper of Dr Weeks, it deals with a *most* important subject Fortunately we are not often called upon to hasten the maturity of the *cataract* In some cases however, where both eyes are about equally affected and advance very slowly and the condition of the *patient* will not allow of waiting for the natural process of *ripening*, we are forced to decide between extracting an immature cataract or attempting to hasten the maturity by some operation Of the various operations that have been devised I think that Förster's is the best and safest Although it will *sometimes* fail to hasten the progress of development it *is attended* with very little danger It will lead to iritis in a certain per cent of cases but the worst result I *have ever* seen was a slight synechia The pupil should be kept well dilated after the operation until all danger has past If the operation fails to hasten maturity it will allow of the extraction of the immature cataract with the greatest possible degree of safety If I were the most ardent advocate of simple extraction, I would make an exception in the case *of* immature cataract I make in all cases a preliminary iridectomy, and after all irritation has completely subsided and the eye has perfectly recovered from the effect of the operation, if it has failed to produce ripening of the cataract, I then extract the immature cataract, making a peripheral incision in the capsule as a still further safeguard against dangerous reaction from any lens matter that may remain in the eye

Dr Herman Knapp, New York—As to heat producing cataract, I know of one case where I produced a cataract by the galvano cautery point with which I burned off the apex of a keratoconus too cautiously, i e, too slowly pierced the cornea I *wanted to make only* a very *small puncture in the cornea* I obtained this end, but a slowly developing yellowish cataract was the result and had to be extracted Whether outward heat for instance, in fireworkers, is a *notable factor in* the development of cataract, I am not prepared to say About thirty years ago, I saw a lens of a diabetic patient rather quickly become *opaque and soon after* clear up The observation though not fully accurate has remained vivid in my mind, and ever since that time I have watched the progress or regress of cataract, but the above example has remained the only one, and therefore has no appreciable value *Unripe cataracts not infrequently* place us in the alternative of removing a cataract prior to the time when the patient's chances of a good recovery are greatest, or to let a patient wait an indefinite length of time for that most favorable period The vogue into which the ripening operations have come is thus easily accounted for They would be a godsend if their action were certain and free *from danger* Unfortunately many an operation for ripening has been done without producing any effect, on the other hand, these operations have proved injurious by provoking iritis and its consequences, and some by a degree of deleterious *morbid process (plastic and purulent irido* cyclitis and panopthalmitis) Even if these mild or severe reactions occur only exceptionally, we are mortified to have created by our own hands any conditions that dim by complications the chances of the patient, when the chief operation, the extraction, has to be undertaken I, for my part, thus prefer the risk of dealing with remnants by a secondary discis*sion, to* the double operation of ripening and extracting the lens which in a majority of cases requires a subsequent division also to clear the pupil

Dr Joseph A White, Richmond, Va —In regard to Dr Baker's paper on the *etiology of cataract, I am satisfied* that the explanation of Dr Risley, attributing the opacification of the lens to disturbance of its nutrition by pathologic processes in the uvea, especially the choroid, is correct in a large number of cases, while not generally applicable All of you, as well as I, have examined many cases *of* cataract after extraction where there was no choroidal disease nor any other evidence of a pathologic process inside the eye, and consequently I am satisfied that there are many cases of cataract in which the etiology is to us an undiscovered factor, and that much yet remains to be found out in regard to this subject Why in one person an opacification *of the* lens remains stationary and in another is progressive, is also a question *yet to be solved* That this is true we well know *for in* zonular cataract we have it progressive in one, and stationary in another case Why can not therefore, opacification of the lens remain stationary in adults? I know *of* a case of a young man who received a blow in the eye several years ago, *which* by *contra coup* without wound of the cornea, ruptured the iris at its pupillary edge and also the capsule of the lens in direct line with the iritic wound A small opacity of the lens developed at this point and to this day remains stationary Cataract has not followed nor has the *opacity* disappeared As to the disappearance of lenticular opacities I have had very little experience, my *only* case being the one referred to by Dr Baker This case was one with marked anterior central opacity of the lens sufficient to materially decrease vision, and cause a semi blindness with a contracted pupil He wished to have the cataract removed and submitted to the ripening process of paracentesis and external massage with great hopes of having a ripe cataract *in a few weeks* His next visit showed a decided diminution in the size of the opacity I triturated the eye again Result three weeks later, a perfectly clear lens Now either this opacity of the lens disappeared or *I made* a mistake, but every precaution against an error had been taken The pupil was gray when it was contracted and there was no ophthalmoscopic reflex with dilated pupil, the *fundus* was illuminated around the opacity and the vitreous was clear The *opacity moved* up and down, with the eye locating it either in the anterior part of the lens or the cor*nea* and it certainly was not in the latter, hence I concluded that it was a case of partial opacification of the lens that had cleared up, how or why, I don't know, what the massage had to do with the result I am unable *to say Like* other sclerosing processes, and I suppose we may so consider cataract, *it may* come to a standstill or it may even retrograde toward recovery, although such cases are rare To discuss Dr Weeks' paper would take more time than is allowed me I have already, however, gone on record to some extent in regard to immature cataract I presented to this body a paper on that subject several years ago in which I suggested the adoption of a simple process of ripening immature cataracts by paracentesis and external massage without iridectomy, because I had had bad results in Förster's operation from iritic processes I reported a number of cases then and have done others since, and have had exceptionally good results—no bad ones I have been lucky, I suppose Like Dr Knapp, I think the less traumatism an eye is subjected to the better, and hence I never ripen an immature cataract if the case will wait for nature's processes, and then only if the patient is under 60 years of age, because I thereby break up and loosen the cortex from the capsule, simplifying the extraction Over 60 years of age, I extract without waiting for maturity, but it is difficult to say what the latter signifies, as it does not mean the same to each one of us For instance, a patient may be too blind to move about with assistance, and the cataract be still immature, and again sight enough to see large letters may be present, and the cataract be perfectly ripe, This especially applies to those amber tinted cataracts in old people which never become perfectly opaque and hence relatively are immature, while in reality they are perfectly ready for extraction

Dr J L Thompson, Indianapolis—I wish to say that I have seen a well-marked unmistakable case of cataract disappear spontaneously I had every opportunity of watching it for years before and several years also after the clearing up of the lens As I have published the case with all of its complications, I shall only add that this case of spontaneous cure of a cataract by liquid degeneration within the capsule was more clear to me than is the well known fact that this world of ours revolves upon its axis

Dr James A Lydston, Chicago—A few points bearing on the subject matter as presented in the paper, suggested themselves as the paper was read and discussed I believe that we go a little too far in assuming in all cases in which lenticular opacities disappear, that we have a true cataractous formation, for we know that cataract exhibits a process peculiar alone to itself during the formation stage and, indeed, one that is quite characteristic Becker has done more to enhance our knowledge with respect to cataract than any other investigator in this line, and he has shown that primarily cataract develops by the formation of vacuoles as little air chambers distributed through the lens structure and that these subsequently become filled with fluid of a different density from the remaining lens substance, and finally, there is a separation of the nuclear and cortical portions of the lens from the lenticular capsule constituting light cataract Now in many instances in which lenticular opacities disappear spontaneously, it seems that we are not confronted by a true cataractous formation Still we have opacities occurring in cases in which the capsule has been punctured and subsequently closes Here we may have spontaneous disappearance But I seriously doubt the propriety of accepting the statement that any form of diabetic cataract ever spontaneously disappears, as we know such changes only assert themselves in the later stages of diabetes when our case is almost beyond redemption We have cataract arising from large doses of naphthalin or ergot and those arising from concussion, etc, and it seems that possibly these are the types of cataract, erroneously so called, which are capable of spontaneously disappearing and which are all grouped under the heading of incipient cataract

Dr F C Hotz, Chicago—My experience with the ripening processes of immature cataracts has not been satisfactory In some cases no change in the lens was produced, in a number of cases the manipulation was followed by more or less decided cyclitic irritation I have many years since given up all attempts at ripening, and have not felt induced to return to the attempt even by the favorable report Dr White gave of his cases at the Detroit meeting As to the extraction of immature cataract, I find the operation does not involve greater danger than the removal of a fully mature cataract, provided there is not a very large amount of absolutely transparent lens matter But where this is the case the patient's vision is usually still so good that there exists no urgency for an operation In the slowly progressing opacification which starts in the cortex and therefore early causes great disturbance of sight the lens seldom, if ever, becomes absolutely opaque It appears quite opaque at focal illumination but proves transparent for the ophthalmoscope so that the fundus can be seen although through a mist In this form of cataract the whole lens is a piece of yellowish jelly and it comes out *in toto*, leaves a clear pupil and the healing is as smooth as after the extraction of a ripe cataract

Dr S D Risley, Philadelphia—Dr Baker has very courteously noticed my published observations regarding the etiology and treatment of incipient cataract I rise to call attention to a single point in which he has failed to interpret quite correctly some ambiguous sentence in my paper on the subject While in the eighty cases of incipient cataract there reported, it seemed the treatment addressed to the choroidal disease had arrested the progress of the opacification of the lens I think it is stated there that in no case had I witnessed the disappearance of opacities already formed

Dr A J Erwin, Mansfield, Ohio—At the Detroit meeting in 1892, I read a paper on this subject, in which I brought forward ten cases that I had treated in periods of from four to ten years previous to that time, in which there had been no increase of the opacity from the time treatment was begun Since then, one-half of those cases have died, and none of them required an operation of any kind for cataract during life Four are living and under my observation, one has disappeared In these four cases no increase of opacity has occurred as yet In one-half of the cases there was at least one opaque lens—mature cataract I think that some of them belong to that class of cases that never will mature There was not much improvement although some amount of vision in nearly every case, but there appeared to be a complete stopping of the advancement of the opacity My treatment as I gave it on that occasion was iron tonics, with cleansing and iodin applications about the eye I have made up my mind since that the application of weak solutions of iodin applied daily in some cases is the most important part of the treatment, and that the best solution is that of about one half the strength of the officinal tincture

Dr Dudley S Reynolds, Louisville, Ky—It is unfortunate that gentlemen who speak of stationary opacities of the lens fail to state more definitely the character and precise location of those areas of opacity We are all familiar with the peripheral opacities of the lens observed in childhood and remaining nearly stationary through life to advanced age Traumatic opacities of the lens often remain distinctly circumscribed for years I have in mind the case of a student who has a foreign body encysted in the upper portion of the lens, midway between the periphery and the vertex, and which has remained more than four years without any disposition to increased opacity beyond the small area of the wounded portion

Dr J E Weeks, New York—I am glad to hear the expressions given against the artificial methods of ripening cataracts I think it will not be long before such methods will be entirely abandoned

---

PRACTICAL POINTS IN ANESTHESIA FOR PLASTIC OPERATIONS ABOUT THE EYE

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore, Md, May 7-10, 1895

BY M W ZIMMERMAN, M D
PHILADELPHIA, PA

A perfect anesthetic would render the patient completely insensible to pain, without in the slightest degree endangering his life Unfortunately this has not been discovered, and we must select that which best meets the requirements of the particular operation to be performed I shall avoid entirely discussing the broad subject of anesthesia with its relations to surgery in general, and confine myself to some of the practical problems presented by operations about the eye

Those plastic operations which come within the scope of the ophthalmic surgeon involve tissues controlled by the very mobile facial muscles, and it is desirable to avoid the disturbance of relation which would result from their activity

Again, operations of this class, for cosmetic reasons, and because they usually have for their object the preservation of the eye, require great care in the selection and adjustment of flaps, and consume much time As a consequence of these facts, they demand complete and prolonged insensibility, with the least possible danger to life The value of unconsciousness in operations about the eye must not be forgotten, it prevents mental suffering and possible interference on the part of the patient

Beginning with the general anesthetics by inhalation, we have in nitrous oxid gas, an agent which meets two of our conditions perfectly, but by reason of the very transient character of its effect, is only suitable for the most trivial operations The contest between chloroform and ether for acceptance as the general surgical anesthetic, is still in progress with slight hope of an early final decision, but we will be safe in assuming that ether is distinctly safer for prolonged administration The marked early irritation of the fauces, and greater tendency to produce nausea, do not weigh against the decreased risk Bromid of ethyl has had a revival recently, it possesses most of the good and all the bad qualities of chloroform, death has certainly resulted from its use

As the imposed conditions of complete and prolonged anesthesia, with the minimum of danger, seem to be best fulfilled by ether, it will be proper to discuss briefly its administration where this bears upon our subject In all details of surgery, the personal equation is large and the particular kind of tool is of minor importance There are, however, practical points which should be considered The region involved, especially when dealing with the lower lid and cheek, is so near the respiratory openings that large or complicated inhalers are to be avoided My own experience while house surgeon at Wills Eye Hospital, led me to depend entirely upon two layers of a coarse, soft towel, which can be very readily molded about the mouth and nose without encroaching upon the field of operation The moistened center of the towel directly over the nostrils and mouth should, for mechanical reasons, be kept from actual contact with these openings This simple method has the great additional advantage of surgical cleanliness, as fresh towels can be substituted whenever vomiting or the regurgitation of mucus make it desirable I am quite sure that many operative wounds have been infected by inhalers, which owing to their size and rigidity, could not be kept from contact

Of the available methods for producing insensibility, limited to the locality of operation, the simplest is that of freezing by the direct contact of salted ice, which has a limited field of usefulness in preventing the pain from applications of the cautery, and like rapid measures It is, however, unfit for prolonged plastic work The various freezing methods by spraying volatile liquids, as ether, ethyl, chlorid and rhigolene, are distinctly more readily adopted to varying conditions of contour and extent of surface, but have the same limitations The peculiar difficulty in protecting the eyeball from irritation, and the brief duration of the effect are the main objections Even when used with the greatest care, the intense cold produced by these sprays sometimes does notable damage to the skin, and the nutrition of future flaps must always be more or less endangered

Concerning the induction of local anesthesia by forcible infiltration of the tissues with benign solutions, little need be said The method is ingenious and an addition to our resources in cases where for any reason both cocain and general anesthesia are impossible It presents most of the objections applying to the subcutaneous use of cocain, while the fact that insensibility is limited to the actually edematous tissue, render it useless for the class of operations being considered

Cocain remains at the present day the one local anesthetic agent which has stood practical tests Other substances undoubtedly possess the power of more or less completely abolishing the sense of pain in tissues to which they are applied, but for various reasons they are of purely theoretical interest Tropococain, a very closely allied drug, has excited some interest, but the slight advantages claimed for it are not established For plastic operations wholly within the conjunctiva, pain may be entirely abolished by using locally a 3 to 5 per cent aqueous solution of cocain muriate, the ready penetration of the solution into the sub conjunctival tissues rendering injections into the latter unnecessary Gelatin disks and oily solutions are unsuitable Where the skin is invaded to a limited extent only, and the operation is of a kind to permit rapid completion, as in canthotomy, this simple method will suffice The well-known effect of the prolonged action of cocain upon the corneal epithelium may be modified by occasionally moistening the latter with a solution of boracic acid

Absorption of cocain solutions by the skin is very slight, and applications to it produce practically no effect This is even true concerning long contact of strong solutions with the carefully prepared and extremely thin integument of the lid so that the possibility of operation depends largely upon the patient's endurance Subcutaneous injection however, may cause a very complete anesthesia of all immediately surrounding tissues The extent of its influence depends principally upon the anatomic peculiarities at the point of injection, and, broadly speaking, bears inversely a close relation to the density of the tissues The superficial layers of the skin are always last to lose sensibility, hence the injections should, when possible, be made directly into it About the eyelids, however, the skin is so very thin and so readily affected, that it is of less moment The needle punctures are painful, and their number should be reduced as much as possible by employing a long needle and thrusting it in the direction of the projected incision By gradually emptying the syringe during its withdrawal, a considerable region can be reached at each puncture This familiar procedure is of great value, especially when for any reason general anesthesia is undesirable, but there are several drawbacks to its routine use Owing to the number of punctures required, and the peculiar construction of the injecting syringe, the greatest care is necessary to prevent the introduction of septic matter, and consequent serious interference with the healing process The danger of serious results from such a mishap is of course greater where the tissues are subjected to violence of the kind necessary in transplantation

Another objection is based upon the violence done the tissues by forcibly introducing an irritating fluid, the chemical and physical effects of which must influence unfavorably the nutrition of the flaps In the various forms of grafting this objection holds with peculiar force, because here the one grave danger is death of the graft While the matter is to some extent one of idiosyncrasy, and not easy to anticipate, the danger of serious and even fatal intoxication by cocain must be guarded against by using solutions not exceeding 2 per cent in strength, and never injecting more than 2 to 2 5 grains The recumbent position also decreases the danger Finally, it should be remembered that cocain has little power over very hyperemic and inflamed tissues Very briefly then, my conclusions may be stated as follows

1 Plastic surgery about the eye requires complete and prolonged anesthesia with the minimum of risk to the patient, and which can be induced without impairing the life of the tissues, or infecting the wounds

2 Ether, among general anesthetics best meets these demands The method of administration should be simple, cleanly, and avoid encroaching upon the field of operation

3 Cocain is the only suitable local anesthetic For the conjunctiva it may be applied to the surface in 2 to 4 per cent solutions When the skin is involved, subcutaneous injection becomes necessary The punctures should be few and the dose not exceed 2 5 grains

TRANSPLANTATION OF SKIN IN PLASTIC OPERATIONS ON THE EYELID

Read in the Section on Ophthalmology, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md, May 7-10 1895

BY WALTER B JOHNSON, M D

PATERSON N J

The transplantation of skin flaps in plastic operations upon the eyelid, by the method in vogue at present, is the result of a gradual development in the size of the portions of new tissue to be transplanted The method of supplying new dermal tissues where loss of skin had resulted from accidents, burns or other causes, was originally introduced by Prof J L Reverdin, of Geneva, Switzerland, in 1869 It was called "skin grafting," and consisted in the application to granulating surfaces of very small portions of epidermis snipped from the skin of a living subject, care being taken that the dermis should not be included in the graft The grafts were applied to the diseased surfaces and resulted in the formation of new cicatricial tissue, which was undoubtedly the product of the proliferation of the transplanted elements Thiersch, Pollock, Bryant and others adopted the method, increasing the size of the grafts and including the cutis as well as the cuticle, believing that the proliferation occurred from the dermis as well as the epidermis Fiddes reported cases in the *Lancet*, of new tissue formation resulting from the proliferation of epidermal scales scraped from the skin by a long bistoury The method rapidly came into general use, it is, however, only skin grafting, the implantation of a nucleus for the formation of cicatricial tissue and not transplantation of true skin

The implantation upon granulating or fresh cut surfaces of large skin flaps from adjoining parts was introduced by Tagliacozzi many years before the possibility of skin grafting was thought of He carefully dissected a portion of skin from a point near the surface to be covered, retaining at its base a pedicle through which the flap was to receive its nutrition Modifications applicable to various locations were suggested by different operators The procedures recommended for the plastic surgery about the eyelids were not wholly satisfactory, in consequence of the unsightly cicatrices at the point of removal of the flap, the thickening about the pedicle and the frequency of ulcerative processes intervening, which resulted in still more serious deformity than existed prior to the operation

In 1878, Mr J R Wolfe, of Edinburg, reported in the London *Medical Times and Gazette* of June 3, a new method of "the transplantation of skin flaps from distant parts without pedicle" Following this, operations were successfully performed and reported by Wadsworth, Noyes, Aub, Mathewson and others The many advantages of the procedure led to its immediate adoption by ophthalmic surgeons The object of the operation is the transplantation of healthy skin flaps to the required situation, the agglutination and healing by first intention, the permanent adhesion of the healthy new tissue at the point of implantation, and the relief of the existing deformity

The skin selected for transplantation must, as nearly as may be, approximate the conditions and quality of the skin at the location to which it is to be transplanted, an allowance of fully one third must be made for shrinkage of the flap, all areolar tissue must be carefully removed, the flap must be dipped in tepid water and then thoroughly dried, the site of operation must be carefully prepared, and if the transplantation is to be made on the day of operation, all small blood clots and other detritus must be removed In some cases it is desirable, especially if arteries have been tied, to allow an interval of two or three days to elapse between the time of the preparation of the wound and the application of the flap, as sepsis may affect the flap if sloughing of any of the tissues occur Before transplantation the granulating surface must be very carefully washed and dried, the prepared flap is then applied and gently pressed into position where it will adhere like sticking plaster The wound is then dressed, no sutures are recommended, although in many of the cases reported, catgut or other sutures have been used, sheet lint compress and bandage is applied and allowed to remain *in situ* for four days Great care should be used in removing the dressing, lest the flap be torn from its new adhesion by dragging Gold beater skin plaster is often used next to the flap

The following case was operated upon successfully by the Wolfe method

H T, age 3, colored Applied at the Paterson Eye and Ear Infirmary for treatment, stating that six months ago he had received an injury of the right eyebrow from falling upon a stone step The injury was followed by excessive swelling and subsequent inflammation The family physician made an incision and a large quantity of pus was evacuated The wound closed on two occasions and re-incision was necessary Extensive destruction of the skin of the upper eyelid resulted from ulceration which occurred during the stages of acute inflammation and was never at any time entirely healed The contraction of the cicatricial tissue thus formed produced complete eversion of the upper eyelid as shown in plate No 1

August 2 Upon admission, the child was in apparently good physical condition There was eczema about the face resulting from the excoriation of the ichorous discharges from the eye The ectropion of the right upper eyelid was so extensive that cicatrical tissue about 3 lines in width separated the ciliary margin of the lid and the eyebrow The everted palpebral conjunctiva was swollen, thickened and rough, bleeding upon the slightest touch Almost all of the retro-tarsal fold was exposed and it nearly concealed the eyeball, there was a deep central ulcer of the cornea and a constant discharge of thick muco-pus

The patient was etherized and an incision made, exposing the frontal bone which was diseased The carious bone was removed and the wound dressed After the opening closed, the ulceration healed, the swelling of the lid decreased under proper diet and palliative medication The cicatricial contraction resulted *in an increased eversion of the lid*

September 25 The patient was again etherized, and an incision was made midway between the brow and the edge of the lid $1\frac{1}{8}$ inches in length, the lid was carefully dissected, the attachment of the cicatricial bands divided and the edge of the upper lid stitched to the lower The result of this procedure was a large gaping wound $1\frac{3}{8}$ inches in length and $\frac{7}{8}$ inch in width in the median line An elliptical incision was made on the inner side of the left thigh $2\frac{5}{8}$ inches in length and $1\frac{1}{4}$ inches in width at the largest diameter of the ellipse The skin within the lines of the incision was carefully dissected from the leg and all areolar tissue removed After preparation, the flap measured nearly two inches in length and about one inch in width in its widest part The flap and the wound were rendered aseptic, four fine catgut sutures were used to unite it to the edges of the wound, gold beater skin plaster was then placed over the new lid and the eye dressed with a compress bandage

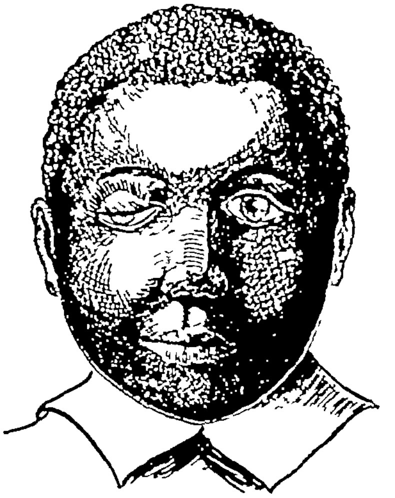

Figure 1

September 29 The dressings were removed, care being taken to prevent dragging upon the flap, the stitch uniting the eyelids and the stitches from the end and center of the flap were carefully cut and drawn out The transplanted skin flap seemed to have united in its new location although it presented a grayish appearance, externally, which looked like semi-transparent glass The pigment deposit in the deeper layers was so dark that it appeared as if sloughing of the entire flap was imminent There was no purulent discharge The eye was dressed with plaster and bandaged as before

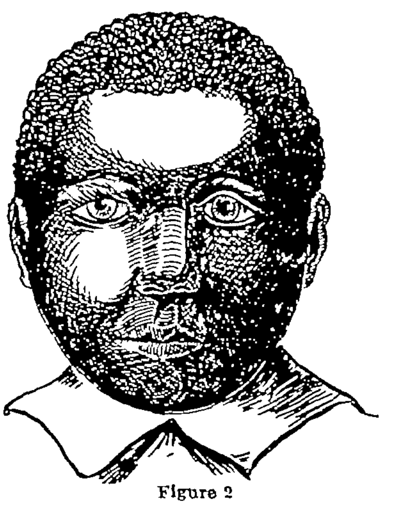

Figure 2

October 2 The dressings were again removed and a thin gray membrane nearly the size of the flap came away with the plaster This was at first believed to be the flap itself On closer inspection however, the entire surface of the new lid presented a peculiar appearance of semi granulation points of reddish color The excessive pigment deposit having materially lessened, a glazing which seemed to be the result of a deposit of thick viscid mucus indicated the *formation of a new layer of epidermis* The dressings were reapplied

October 4 The eyelid when exposed disclosed the presence of a grayish membrane with commencing pigment spots which covered the entire field of the operation

October 6 The membrane has assumed the appearance of newly formed skin, the lid maintains its natural position, there has been very little purulent discharge during the recovery After this date the skin became more natural in appearance, softness and pliability No unfavorable symptoms occurred There was complete relief of the deformity The eyelid could not, however, be elevated to the extent of that of the fellow eye The accompanying plate, No 2, illustrates the condition six weeks after the treatment was discontinued

SKIN GRAFTING ON THE EYELIDS

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore, Md , May 7 10, 1895

BY F C HOTZ, M D

PROFESSOR OF OPHTHALMOLOGY IN CHICAGO POLICLINIC
CHICAGO

Skin grafts play an important rôle in the plastic operations upon the eyelids, they are especially serviceable in certain forms of ectropium and entropium

1 *Skin Grafting in Ectropium* —If the destruction of the integument of the eyelid has been so extensive as to result in a more or less complete ectropium, the lid can not be restored to its normal position unless it be provided with a new integument

The material for this new covering may be obtained from three sources, to wit we may transplant upon the lid a skin flap from the vicinity, or we may graft upon it a piece of skin from the arm (Wolfe's method), or we may cover the whole defect with Thiersch's grafts

If executed under the proper aseptic precautions, these different plans are probably equally successful as far as the immediate healing of the implanted material is concerned And those who are satisfied with their work as long as it removes the ectropium, no matter how the eyelid may look after the operation, consider one method as good as the other But we come to a different estimate, if we demand of a plastic operation in the face that it should not only relieve the pathologic condition, but also restore, as well as it is possible, the normal appearance of the parts, or, in other words, that we should not be satisfied with the mere removal of the ectropium, but insist that the operation should also give back to the lid its normal shape and mobility

The normal integument of the eyelids is a thin, soft and light cover which snugly adapts itself to the contours of the lid and to all its movements, which play so important a rôle in the facial expressions It is, therefore, very essential that the new substitute possesses all these qualities of the original lid skin it must be thin and soft, in order to bring out the normal shape of the lid, and it must be light, so as not to impede by its weight the movements of the lid This latter condition is of particular importance in the operation for ectropium of the upper eyelid Skin flaps taken from the vicinity occasionally—but very rarely—possess all the conditions necessary for a perfect cosmetic result, usually they are too thick and too heavy to make a nice looking eyelid The same objections apply to Wolfe's flaps, which, in my opinion furnish the least suitable material and should never be employed for plastic work on the upper eyelids

There remains then for our consideration Thiersch's skin grafting operation, which I regard as a priceless accession to plastic surgery, for it has solved the difficult problem of repairing the eyelids with a material possessing all the important attributes of the lid skin, and it gives us results in every respect superior to what can be achieved by the transplantation of skin flaps

How skin grafting should be executed, what rules and precautions should be observed to attain the best results, I think, can best be shown by briefly describing the way of proceeding in a case of ectropium of the upper eyelid An incision is made through the cicatricial tissues along the line of the border of the everted lid, and while the lid border is then drawn downward, all resisting cicatricial bands are cut transversely by gentle passes of the scalpel This dissection is continued until the lid can be easily inverted and its free border can be drawn downward far beyond its normal position so that it describes a convex line In this position the lid border must be fixed during the healing process, and this is accomplished by three ligatures, which are passed through the lid border and securely fastened on the cheek by adhesive plaster strips But if there exists, *also*, an ectropium of the lower lid of the same eye, I pass the ligatures through the border of the everted lower lid and tie to it the border of the re-inverted upper lid

The object of thus fastening the operated lid is twofold 1, to make the surface which is to be covered with skin grafts, so large that the new lid skin will not become too short by the subsequent inevitable contraction of the tissues, and 2, to keep the lid immovable during the healing process, because any movements would displace or wrinkle up the grafts and render impossible their adhesion to the lid surface

When the lid is properly fastened, the wound is temporarily covered with a gauze compress wrung out of a 5 per cent salt solution, and we proceed with cutting the grafts The most convenient place to take the grafts from is the right or left arm The arm we intend to operate upon has several hours previously been thoroughly washed and scrubbed with soap and water and wrapped in a compress wet with the salt solution The bandage being removed, I grasp the arm firmly with the left hand, in order to hold the skin well stretched between the thumb and the fingers With my right hand I seize the razor, lay its blade flat upon the well wetted surface of the arm and press it down just enough to make its sharp edge bite into the skin, but no deeper than the papillary layer By slow and short sawing movements the blade is now steadily pushed on in the papillary layer until a piece of epidermis of the desired size has been gathered on the razor blade During this "shaving process" my assistant is dropping salt solution upon the blade and pushes with a probe the skin shaving back from the edge of the razor When I wish to cut the shaving off, I turn the edge of the knife a little up, while my assistant presses the probe flat down upon the shaving near the edge of the razor blade Now the compress is removed from the lid, the wound is carefully cleansed of all coagulated blood and the skin shaving is transferred directly from the razor to the lid surface For this purpose plenty of salt solution is dropped on the razor to keep the graft floating, if, now, the edge of the razor near its point is brought in contact with the border of the wound, the solution will run off from the razor and carry the graft with it, but as soon as the solution begins to flow and the edge of the graft has come in contact with and clings to the wound border I slowly draw the razor from under the graft across the wound, by which maneuver the skin graft floating from the razor is at once spread out smoothly over the lid surface

Some advise to place the grafts as they are removed, in salt solution until the requisite number is cut and then transfer them from the solution to the lid I regard this as an unnecessary complication of labor, for in the solution the grafts curl up, and it takes then a great deal more time to uncurl and spread them out smoothly than if they are transplanted directly from the razor to the wound

It is not necessary to cover the whole wound with one single graft, but, on the other hand, I think better results are obtained if the grafts are few and large than if they are very many and very small It is not difficult to cut shavings from one and one-half to two inches in length and from one to one and one-half inches in width, if only the knife blade is operated by a steady hand and moved in the same plane

When the whole wound is well covered with these skin shavings, I cover them with two layers of strips of silk protective moistened with the salt solution, they are one-half inch wide and long enough to lap over the wound border on both sides, one layer is placed in a transverse direction and the second layer in a longitudinal direction These strips are covered with a compress which is to be kept wet with the salt solution, and finally a bandage is put on the well eye also, to stop all movements of its lids, because thereby alone we can insure the absolute rest and immobility needed for the operated eyelid during the healing process

This first dressing remains undisturbed for two days at least To remove it the compresses and strips of protective are thoroughly wetted with salt solutions, the grafts are rinsed with the same solutions, and fresh strips and compresses are put on After four or five days the good eye may be left open, after one week the ligatures may be removed, and during the second week the grafted lid needs only to be daily rubbed over with iodoform ointment, for at this period there is a constant desquamation going on and the lid becomes uncomfortably stiff and crusty with exfoliated epidermis scales unless the surface is kept well anointed After the second week no further treatment is required The grafted skin undergoes a gradual contraction of about one-fourth of its area, but if this shrinkage has been anticipated by the operator, it will not affect the perfect cosmetic success of the operation

2 *Skin Grafting in Entropium* —The correct position of the eyelashes is so thoroughly dependent on the presence and correct positions of the free border of the lid that no permanent relief of entropium can be attained by any operation which fails to reconstruct the lid border As long as the tarsus is thin and elastic, the inverted border can be successfully turned back to its normal position by the operation introduced by me in 1879 But in the higher degrees of entropium, the tarsal cartilage has usually undergone structural changes and lost its elasticity to such a degree that its rigidity is a serious obstacle to the turning back of the free border Under these circumstances the re-position of the inverted lid is possi-

ble only, if a wedge-shaped piece is removed from the cartilage This operation, however, can be carried out successfully only in cases where the tarsus has sufficient thickness to allow the removal of a wedge of the requisite size, but in many cases we find the cartilage so thin and small that the cutting of a sufficiently large groove is impossible Under these circumstances skin grafting helps us over the difficulties, for if we can not turn back the inverted lid border, we may turn up the eyelashes and support them in their correct position by an artificial lid border made of a skin graft And although I myself once advocated a grooving operation[1] I have abandoned it, because I have convinced myself that the creation of a new lid border answers our purpose much better and is a less tedious operation than the grooving, beside it can be used in all cases of extreme entropium

The first attempt at creating an artificial lid border is found in Spencer Watson's operation, from this crude beginning the operation has been gradually improved by a process of evolution in the various transplantations of Gayet, Dianoux, Jacobson and others, until skin grafting has brought it to its present perfect and simple form

It is executed in the following manner the lid border is split into an anterior and posterior layer by the well-known intermarginal incision which is made so deep that the anterior layer can be turned up with perfect ease

Now I make a transverse incision through the lid skin and orbicularis muscle just below the upper line of the tarsal cartilage, excise the strip of muscular fibers covering the upper border of the tarsus and unite the lid skin with this upper border by three sutures, one suture being placed at the center of the wound and one at either side Each suture passes first through the edge of the lid skin, then through the upper border of the cartilage and finally through the upper skin border of the wound When these sutures are tied, the lid skin is drawn upward and fastened to the upper border of the cartilage, and this traction upon the lid skin is sufficient to cause a thorough eversion of the anterior edge of the split lid border, and when the anterior edge is thus everted and drawn away from its posterior edge, the intermarginal incision is transformed to a gaping wound of several millimeters in depth and with sloping edges This groove is to be filled by a skin graft Sometimes I have used for this purpose a narrow strip trimmed off with scissors from the skin edge of the lid wound, but I prefer taking the graft from the skin behind the ear where the skin is of a firmer texture and where the presence of a smooth bone surface to which the skin is so closely attached is a great assistance in the accurate cutting of these long and slender grafts, for as they are to be but from 1 5 to 2 millimeters in width, it is very essential that the skin does not drag before the knife, because this would make the edges so ragged as to render the graft unfit for use

I first make a longitudinal incision 1 millimeter deep and as long as the graft should be A second incision is then made parallel to the first one at a distance of 1 5 to 2 millimeters according to the width of the intermarginal groove the graft is intended to fill This second incision is made to join the first one at both ends and also to meet it at the depth of 1 millimeter, by giving the scalpel the proper slanting direction The long and narrow strip of skin thus mapped out by the two incisions is seized by a fine forceps, completely dissected off and transferred directly to the lid border which is carefully cleansed from blood coagula before the graft is put in place The graft is spread out and gently pressed into the groove, if it fits accurately, the lid and the conjunctiva are once more irrigated with the salt solution, and both eyes are covered with compress and bandage in order to stop all movements of the lids After twenty four hours the graft is already firmly adhering and the bandage can be left off

Should the graft be too long or too wide, its ends or edges can be trimmed with a pair of fine scissors without taking the graft off from its new resting place

The surface of the graft should be even with, or a little below, the edges of the wound, it should never protrude beyond them, if it does, it is too thick and should be cut thinner To do this, I turn the graft over with its epidermis side down and shave off a little of the cutis with a pair of fine scissors, and then put it back in place

If, after twenty-four hours, the graft is not adherent, it is dead and useless, if it is adherent, the success of the operation is assured During the first two weeks the epidermis of the graft comes off in scales, and it is therefore advisable to keep the new lid border well lubricated with vaselin, lest the dry and hard epidermis scales irritate the eye After two weeks the surface of the graft becomes smooth and can hardly be distinguished from the rest of the lid border

I regard the solid skin grafts described above, a better material for the reconstruction of the lid border than grafts of the Thiersch kind, or of mucous membrane We must not forget the intermarginal wound being an angular groove, has the great tendency of closing up from the bottom and of drawing its edges together This tendency is successfully overcome by filling the groove with a solid graft, but not by only lining it with mucous membrane or epidermis shavings

The use of true skin for grafting has been objected to on the ground that it contains fine hairs which would be a source of irritation to the eye Judging by my own experience, I should say this fear is groundless I have never seen any hairs grow in such grafts and I am inclined to the belief that when such irritating hairs are found, a careful inspection will show they do not grow from the graft, but from the posterior edge of the lid border, they are eyelashes which have been left in the posterior edge when the lid border was split

---

ON THE OPERATIVE TREATMENT OF THE SEVERER FORMS OF ENTROPIUM AND TRICHIASIS

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md., May 7-10 1895

BY HERMAN KNAPP, M.D
NEW YORK

Nothing original is claimed for what I have to say I merely beg to submit to your judgment my preference for a method of treatment, as it has developed by personal experience during years of labor in one of the most common fields of ophthalmology With your permission, I will introduce and exemplify my remarks by the report of a case, the only one I shall report

---

[1] Paper read before the 9th International Medical Congress 1887

Dec 6, 1890, Mrs F W C, of Boston, came to me with chronic trachoma Both eyelids turned in, lashes irregularly scattered over the rounded free margin, many on the inner edge Pannus over the whole cornea V, 20–200 The inner surface of the lids showing an irregular network of cicatrices with projecting islets of swollen mucous membrane between the fiber tracts (xerosis glabra) Palpebral fissure narrowed Constant lacrymation, some mucous discharge, incessant irritation Daily touchings with the sulphate of copper crystal did not relieve her very much

Operation Dec 31, 1890, at the hospital First an ordinary canthoplasty was made to enlarge the palpebral fissure Then a clamp was applied to the upper lid and an incision of about 3 mm carried through the whole length of the intermarginal space It ran from the inner edge of the lid margin, obliquely backward and upward, so as to comprise the cilia and their roots in the outer flap

Then I incised the skin and muscle of the lid 3 to 4 mm above the ciliary border and removed a strip of skin (1 5 mm broad) from the whole upper edge of the incision, and placed it on the sterilized forehead of the patient A small strip of the orbicularis was excised, and a longitudinal wedge-shaped piece cut out of the tarsus Four sutures were passed through the ciliary flap, the upper border of the groove in the tarsus, and the upper skin flap They united the wound, broadened the gap in the intermarginal space, and turned the whole ciliary border of the lid outward After cleansing the groove in the ciliary margin from the blood with a 1 to 5,000 solution of bichlorid of mercury, the skin flap was taken up from the patient's forehead and inserted into its wedge-shaped trough When it was well adjusted and the hemorrhage stopped, the wound was dressed with a patch of corrosive sublimate gauze, greased with benzoate of mercury salve and covered with a thin layer of absorbent cotton, held in position by court-plaster strips

The lady had pain for an hour The dressing was changed daily The implanted flap took root in its whole extent The sutures were removed on the sixth day

The other eye was operated on in the same way, and with the same result The patient was completely relieved She left the hospital on the twelfth day The inner surfaces of the lids were treated with sulphate of copper for some time During the next three years several mild relapses of trachomatous inflammation occurred, which were speedily cured with the copper crystal The restored intermarginal space kept broad and even, no more inverted eyelashes

The lashes stood in a row, all directed forward and upward The cornea had cleared up, the patient could read with ease, and I have not heard her complain since On inquiry a few weeks ago, she answered that her eyes had not given her any trouble She said that for years before the operation she did not know what comfort was

This, Mr President, is the first case I operated on according to this method Since then my hospital associate, Dr R O Born, and myself have operated on a number of severe cases of entropium and trichiasis in the same way with a good deal of satisfaction

The operative methods for entropion are legion For the more marked cases I long ago acquired a preference for the Streatfeild-Snellen operation The method of Jaksche-Arlt, raising of the ciliary border, is very old, having been practiced by Aetius (about 500 A D) and Paul of Egina[1] (about 675 A D) It yields very good primary results, as most entropium operations do, but all the cases I have operated on according to it, showed a gradual shrinkage of the intermarginal space gained by the operation and a return to the previous condition

The different procedures during the last twenty-two years, to combine a plastic operation with the other methods have interested me greatly I tried some of them, for instance, that of Burchardt,[2] of Berlin, which consists in implanting into the split intermarginal space a strip of skin taken from the upper lid over the cilia, the ends of the strip remaining attached In one of my cases an unpleasant ulceration of the cornea resulted Though the method could not be blamed for this occurrence, I have abandoned it, because I was not satisfied with the appearance of the flap shifted over the outer border of the ciliary edge, the ends of the flap remained raised and the intermarginal space was not so regular and even as when a flap without a pedicle had been inserted Flaps with a pedicle seem to have first been used and described by Spencer Watson,[3] flaps without pedicles by Waldhauer[4] He was followed by W T Smith, of Chicago, Ill, "A New Operation for Distichiasis or Entropium (*Arch of Ophthal*, 1887), v Hippel, Fuchs, Franke, Raehlmann (*Deutsh Med Woch*, No 1, 1891)

Dr J M Ray, of Louisville, Ky, who published a case of pedunculated flap in the *American Journal of Ophthalmology*, 1892, p 142, writes me that he has since then tried the transplantation of skin along the lid margin in seven cases, in five of them without a pedicle He says "In extreme cases of trichiasis it has been the best method I have ever tried"

An objection has been made to this method, viz, that the fine hairs which grow on the skin of the lid will after the transplantation irritate the cornea I have not heard patients complain of this condition, but Dr Born has seen hairs coming through the transplanted flap, evidently eyelashes whose roots were left in the posterior (conjunctival) flap He therefore excises these roots before he implants the skin flap

The objection of the hair growing on the transplanted skin flap has determined Lidner[5] to transplant into the incised lid margin a pedunculated flap from the conjunctiva, and Van Millingen[6] and Benson[7] have transplanted unpedunculated flaps of mucous membrane taken from the lips where the mucous membrane joins the skin

I have not tried flaps of mucous membrane, as the skin flaps thus far have given me satisfaction[8]

To recapitulate

In severe cases of entropium and trichiasis, good results can be obtained by an implantation of skin into the intermarginal space of the lid The steps of the operation are as follows

1 Ordinary canthoplasty

[8] I have tried them since The results were good, but no better than with the skin flaps Oct 9 1895

2 Incision of the intermarginal space according to Jaksche Arlt

3 Curved incision of the skin, 3 to 4 mm above the ciliary border Removal of a small strip of muscle along this incision

4 Grooving of the tarsus according to Streatfeild

5 Passing sutures through the lower lip of the wound, the upper edge of the tarsus, and the skin of the upper lip

6 Detaching from the upper lip of the wound, with a straight pair of scissors, a strip of skin, 1 5 mm broad and as long as the incision in the intermarginal space, and implanting it into the gaping and cleansed incision Sutures may be used, but are not essential

7 Tying the skin tarsus sutures, four or five in number The threads may be cut short, or stretched and fastened to the skin above the brow by collodion (Panas) or strips of plaster (Born) if the free edge of the lid is not sufficiently everted

8 Dressing with bichlorid gauze, greased with a salve, or leaving the eye uncovered

9 Cutting the sutures in from three to five days Cleansing the eye every day, very gently so as not to disturb the implanted flap, or leaving the dressing undisturbed for a week The flap in almost every case unites in its whole extent

This plan of operation is to be simplified or modified, according to the conditions of the case

---

CASE OF EPITHELIOMA OF EYELIDS PLASTIC OPERATION, WITH EXHIBITION OF PATIENT

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895

BY HERBERT HARLAN, M D
BALTIMORE MD

After a large number of experiments in the removal of malignant growths affecting the eyelids, or their immediate vicinity, by caustics and various surgical procedures, I have come to the conclusion that the best method is extirpation by the knife and restoration of lid by plastic operation, and as a good example I present the following case

Basil Shipley, farmer, age 60, from Carroll County, Md, was first seen by me March 1, 1892 At that time he had what was evidently (I speak from a clinical standpoint) an epithelioma of inner side of left eye It involved the inner margin of both lids, the upper to about one fifth its extent, and the lower to nearly or quite one-third, and extended over or to the side of the nose Roughly speaking, it covered a surface the size of a quarter of a dollar

Two previous operations had been done, one by a prominent surgeon, and one by a skilled oculist Each operation had been followed by a prompt recurrence, with increase of symptoms

The lacrymal sac and both canaliculi were involved The patient was put under chloroform at the Presbyterian Eye, Ear and Throat Hospital, and the whole mass freely dissected away A very large gaping wound, certainly as large as half a dollar, was left After the bleeding had been pretty well checked, a balloon shaped flap was dissected from the forehead, twisted down and carefully stitched in position with silk I regarded it as quite impossible to preserve any tear duct, and made no attempt to do so The forehead wound was closed by a single row of sutures Iodoform and gauze was used as dressing and the healing was uneventful He returned in March of this year and a small growth down on the nose was burned freely by the galvano cautery The ectropion which you see, while unsightly, I regarded as harmless, and did not advise further operation

DISCUSSION ON PAPERS OF DRS ZIMMERMAN, JOHNSON HOTZ, KNAPP AND HARLAN

Dr R A Reeve, Toronto—My experience with transplantation of flaps without a pedicle was given at the Canadian Medical Association in 1879, I think The first one was largely a failure The technique was not at fault but the patient had psorias and there was hardly enough healthy looking skin on the body to suffice for a flap As, however there was ulceration of the cornea from exposure I operated Another case of double cicatricial ectropion proved very successful I think it is important to maintain the union of the lids for a long period so as to diminish the ultimate shrinkage of the flap In another case the lids were kept united for several years though sufficiently open to permit useful vision The patient had nothing but cicatricial tissue from the chin to the nape of the neck There was complete *ectropion of all the lids, with keloid cicatrices* In using a flap without a pedicle in order to permit wearing of an artificial eye it is desirable to implant it as centrally as possible so as to get the minimum contraction Blepharoplasty by horizontal sliding flaps has given me gratifying results in a number of instances

Dr H V Wurdemann, Milwaukee—Referring solely to the first paper under consideration, I would say that there will soon come a time when *water* not *ether* will be deemed the only suitable anesthetic for nearly all operations connected with the skin The injection of cocain in percentages over .2 per cent (not 2 per cent) is harmful not only to life itself but to the life of the skin flap Injection in higher solutions is radically dangerous and should be abandoned in favor of infiltration anesthesia by injection of harmless fluids into the tissues I will not occupy your time at this moment by any further reference to the matter which I will sufficiently elaborate in the session of Thursday morning

Dr D S Reynolds, Louisville—I would like to have the last sentence of the first paper re read

Dr M W Zimmerman, Philadelphia—Cocain is the only suitable local anesthetic For the conjunctiva it may be applied to the surface in 2 to 4 per cent solutions When the skin is involved, subcutaneous injection becomes necessary The punctures should be few and the dose not exceed 2.5 grains

Dr Reynolds—I noted that point and wanted it repeated that it might be thoroughly understood I have seen a single drop of the 4 per cent solution applied to the conjunctival membrane produce almost instant pallor with cessation of the heart beat I have noted a dangerous reaction repeatedly and it has been referred to by others

Dr E J Bernstein, Baltimore, exhibited a patient When first seen she had lost both upper and lower lids and the entire nose by syphilis, and had a beginning ulceration of the cornea due to lagophthalmus

Dr Lucien Howe Buffalo—In regard to putting the flap in hot water, it would seem to me to be entirely unnecessary when the transplantation is made without difficulty Promptitude seems of considerable importance

Dr J P Worrell, Terre Haute—I have made a number of grafts introducing skin from back of the ear or more frequently mucous membrane from the lip It is rare that one fails to get union When there is entropion I did not find it necessary to make the graft It has seemed to me that if you can make an operation somewhat like Dr Hotz,' with the incision posterior to the ciliary margin, we shall get such a contraction that we will not have a return of the entropion I have some cases operated upon some years ago and the results are still satisfactory I dissect down the skin absolutely to the ciliary margin and remove all of the palpebral part of the muscle, strip the cartilage entirely From the cicatrization that follows I have never yet had reversion to the entropic condition I always do these operations under cocain and have never yet seen a single case of injury from its use I am inclined to think Dr Reynolds' case due rather to shock than to cocain

Dr P D Keyser, Philadelphia, here exhibited a photograph of a case of transplantation for epithelioma of inner canthus operated upon by him over one year ago successfully and in which there had been no return of the entropion I find too that grafts take equally as well on cicatricial tissue as any other

Dr S D Risley, Philadelphia—I have now quite a group of interesting lid cases in which I have done the grafting operation and I expect good results, even though the cartilage has been usually involved I take the graft from the forearm as described by Dr Hotz I do not think there is any call for any more serious operation

Dr G C Savage, Nashville—It is not often necessary to do extensive or bloody operations for entropion and trichiasis, nor can it often be necessary to transplant skin in an inter-marginal incision By means of the entropion forceps devised by myself, the blades of the forceps terminating in a stirrup as wide as a diseased lid is usually long, with a shoulder extending up each arm of the stirrup for one eighth of an inch, to compress the lid margin, a bloodless and effective operation can be done When the lid has been grasped by passing one blade of the forceps beneath, the other on the outer surface of, the lid is easily inverted and held in position At least one eighth inch of the lid margin is included in the fenestrum The forceps are closed tightly by means of a sliding clamp and the pressure thus exerted makes the operation bloodless The knife is used first for making the Burow incision the entire length of the tarsal cartilage and through all structures down to the skin and one eighth of an inch from the free margin This done, a vertical cut is made from either end of the Burow cut, in the lid margin through all the structures down to the skin, and two similar cuts are made at equal intervals between these The operation thus completed the forceps are removed, when there follows a good deal of bleeding The Burow incision widens the lid, my vertical cuts lengthen it, and the two together effect a complete out-turning of the lid margin One or more times daily the lid should be slightly everted so as to make the wounds gap widely that the deposit of new tissue may be as abundant as possible The operation is easy and its results effective

Dr Frank Allport, Minneapolis—In view of the fact that we have in the operation of Dr Hotz a procedure almost universally successful for the relief of entropion, it seems hardly necessary to multiply operations I have used this process for fifteen years and have been almost universally and permanently satisfied with the results In extreme cases it is usually necessary to combine with it a suitable canthoplasty and when thus applied there are but few cases in which satisfaction will not be achieved It is an operation requiring exactness and deliberation and where failures are noted it may be because these elements are wanting

Dr Hiram Woods, Baltimore—In an operation for upper lid entropion, performed yesterday by Dr Savage as he had described his operation, the primary results were excellent As Dr Knapp says, many cases show this good primary result but later relapse This seems specially true of the Arlt operation Green's operation has been used a great deal within the past few years at the Presbyterian Eye and Ear Hospital with excellent permanent results as observed in cases two or three years old

Dr Herman Knapp, New York—I want it understood the mode of operation which I have sketched refers in its whole extent only to extreme cases Canthoplasty is necessary in many cases because by a general shrinkage of the conjunctiva and tarsi, a more or less marked blepharo-phimosis is present When the tarsus shows extensive cicatricial contraction on the conjunctival side and irregular thickening and curving in of its body with no intermarginal space preserved, the excision of a wedged-shaped slice on the outer part of the tarsus and the restoration of the intermarginal space is indispensable The strip of skin can be most conveniently taken from the upper border of the elliptical wound when the sutures are inserted but not tied The strip is then immediately placed into its bed at the edge of the lid I have seen the inter-marginal space thus gained nicely preserved years afterward

---

Exercise for the Weary—The following is from *Puck* Dr Schmerz 'The trouble, Mr Tyers, is that you don't take enough exercise" Mr E Z Tyers "Aw, I confess I don't go in vewy heavy on athletics, doctaw What could you wecommend as a mild exercise to begin on?" Dr Schmerz "H'm! You might stretch your arms over your head when you yawn!"

POST-ALCOHOLISM

BY S V CLEVENGER, M D

Alienist and Neurologist of the Reese and Alexian Hospitals, Chicago,
Late Medical Superintendent of the Illinois Eastern Hospital
for the Insane, and Pathologist of the Cook County Insane
Asylum, Author of 'Comparative Physiology and Psy
chology," "Spinal Concussion," etc
CHICAGO

Ethyl alcohol, spirit of wine, is commercially assumed to be the base of intoxicating drinks, and the purest of these is capable of working great havoc when abused, but the demand for cheap liquor in vast quantities substitutes for portions of the less harmful ethyl or vinic alcohol what is known to chemists as the poisonous amyl alcohol (potato spirit or fusel oil) The aroma or bouquet of liquors is largely due to certain ethers of the more poisonous amyl and butyl alcohols, notably the acetic and valeric, then superadded, all too often, by distiller, rectifier, wholesaler, and especially by the retailer, are sophistications, flavors and perfumes for the purpose of cheapening the resulting compound, which, by the time it reaches the average consumer, contains in addition to the alcohol diluents to increase bulk, articles to give it false strength, fictitious appearance, odor and taste

In the English Licensing Act of 1872 (35 and 36 Vict c 94) there is a schedule of substances called "deleterious ingredients" found to have been used in adulterating intoxicating liquors, they are cocculus Indicus, common salt, copperas, opium, Indian hemp, strychnin, tobacco, darnel seed, logwood, salts of zinc or lead, and alum Since then, ingenuity and cupidity have extended the list indefinitely among dye materials, both organic and inorganic, and there are also added correctives of acidity, such as litharge, lime, soda, potash, astringents like catechu, oak bark and aloe leaves, earths for decolorizing, sweetening agents, and ethers for flavoring Most of these articles are unwholesome, to say the least, and tend to debilitate and otherwise set up depraved bodily states

Chronic alcoholism in its most obvious features is a condition of functional poisoning such as is seen in its production of lethargy, stupidity and acute narcosis Less noticeably, but gradually, it operates as a tissue poison, affecting parenchymatous elements, particularly epithelial and nerve structure, if not to a greater or lesser degree all the cellular components of the body A slow degeneration is produced until the blood vessels are involved in thickening and fibroid changes Oxidation of tissues is checked, since alcohol is consumed in place of the fat, leading to fatty changes which may advance to general steatosis

Dr Magnus Huss, of Stockholm, in 1849 first prominently directed the attention of physicians to the subject of alcoholism, a term he was the first to use He described the paralytic and anesthetic forms of chronic alcoholism, also later referred to by Hammond ("Diseases of the Nervous System," 1881), Ross ("Diseases of the Nervous System, 1885), and other neurologists

Gowers ("Diseases of the Nervous System," vol i, 110, *et seq* 1892) under the heading "Multiple Neuritis," gives still more recent details of these distressing consequences of drinking alcoholics

Magnan (*De L'Alcoolisme des diverses formes du Delire Alcoolique, et de leur traitement*, 1874), Virenque, Hammond and others observed an occasional loss of sensation involving only one lateral half of the body, as in hysteria The other special senses are generally implicated Thus the patient loses the sight of one eye, can not hear with one ear, can taste with only half the tongue, and smells with but one nostril

Gowers (op cit 119), states that alcoholic polyneuritis is most frequently met with and preponderates over all other forms of nerve inflammation It results chiefly from the stronger forms of alcoholic drinks, and especially from spirit drinking It is more common among those who take small quantities frequently, than among those who indulge in an occasional spree, probably because the total quantity is greater by the former It is far more frequent among women than among men, probably three times as frequent Other causes often cooperate with alcohol in exciting polyneuritis, especially exposure to cold, and, in the poor, insufficient nourishment

The symptoms consist in motor weakness, sensory disturbance and incoordination The weakness involves first and chiefly the flexors of the ankle and extensors of the wrist and fingers in the forearm, the result is wrist-drop and foot drop Other muscles suffer in severe cases The sensory symptoms are tinglings, pains, varying in place and degree, tenderness and loss of cutaneous sensibility The incoordination resembles that present in the slighter forms of locomotor ataxia

Neuritis is the most common finding in chronic alcoholic autopsies

Catarrh of the stomach with furred tongue, heavy breath, a feeling of epigastric distress or "sinking," impaired appetite and constipation are ordinarily experienced

The liver may undergo changes leading to various *forms of cirrhosis* Sometimes moderate drinking may reveal a special liability to hepatic cirrhosis, while, on the other hand, hard drinking for thirty years may leave the liver nearly *intact*

The stomach and liver disorders of drunkards produce dilated veins of the cheeks and nose, causing suffusion of those parts, acne rosacea The eyes are watery, the conjunctivæ hyperemic and often tinged with bile

Formad claims that the kidneys are hypertrophied without other change as a rule, and Guy's Hospital Reports verify this finding Pitt places this as occurring in 43 per cent of hard drinkers, and where the typical granular kidney occurs it is indirectly caused by arterial changes (Osler, "Practice of Medicine," 1001, 1892)

The greatest variability in general manifestations can be found in different patients amounting to idio syncrasies in particular cases, and in other *patients* are classifiable into groups of a great or less number

The *organic changes seem to be erratic*, but are according to the resistance of organs As a forerunner of serious alterations in the spinal cord, neuritis is not a simple and harmless disorder

Magnan has demonstrated an alcoholic paraplegia in which Buzzard found electrical degeneration reaction Some cases end fatally, though Bramwell ("Diseases of the Spinal Cord," 307, 1884), considers it for the most part functional Broadbent's description (*Medical Times and Gazette*, Feb 16, 1884), in which myalgic pains, hyperesthesia and double *wrist-drop* is included, should be compared with the pathologic changes found by Eichorst, of Zurich (London *Lancet*, May 19, 1888), attending alcoholic neuritis, in cases of incoordination followed by paraplegia and wrist-drop, tenderness of muscles, anesthesia, abolition of reflexes and, finally, vesical and rectal paralysis The pathologic anatomy consisted in cord hemorrhages in the dorsal gray, thickened, blood vessels, degenerated and atrophied tibial and radial nerves with axis cylinders destroyed, the peripheral extremities were worst diseased, connective tissue proliferations of endo- and perineurium and *inflammatory changes* in their vicinity A muscular atrophy was secondary to the neuritis, the nerve sheath inflammation extended to the interstitial muscular tissue Bramwell notes that myelitis and other forms of organic disease may be caused by *alcoholic excess, hence the* paralysis may be permanent and incurable

The enfeeblement of judgment and will may finally end in dementia

Post-mortem does not show any particularly characteristic changes in the nervous system *invariable* for all cases of chronic alcoholism, showing that resistance is greater in some than in others Some times hemorrhagic pachymeningitis is observed with thickening and opacity of the pia arachnoid membranes and wasting of the convolutions, or there may be a chronic encephalo meningitis with membrane adhesions, but most of these pathologic states are in advanced cases of alcoholism, the more incorrigible sort, as can be readily believed when we note the fact of many chronic drunkards having been reclaimed and restored to the world about as they were before the habit was formed The older the patient and the longer the addiction, the greater probability would there be of finding organic changes in the brain and its envelopes and blood vessels

Many chronic alcoholic insane exhibit remarkably close resemblance of symptoms to those commonly found as the result of injury to the brain, in traumatic insanity These symptoms are changes of character, lapses of memory, headaches, sleeplessness, irritability, suspiciousness, long apparently lucid intervals, homicidal and suicidal impulses, delusions of persecution These peculiarities appearing in the alcoholic insane long after being incarcerated in an asylum, during which time no intoxicating liquor has been taken by them, point clearly to organic brain destruction, accomplished from within, but as severe and hopeless as when the brain had been injured by a blow upon the head, with subsequent extension of inflammation to the membranes and cerebral tissues

It is when the mental degradation which temporarily occurs in alcoholism becomes permanent that chronic alcoholic insanity may be said to exist During the acute stages there may be hallucinations, illusions and delusions which disappear on recovery from the blood poisoning, the persistence of some of these states betokens permanent damage to the mental apparatus, and the brains of the chronic alcoholic insane invariably exhibit evidences of destructive organic changes

It is with astonishing frequency that jealousy of the wife or mistress exists to an exaggerated degree in most forms of drunkenness, from simple suspicion to delusions of marital infidelity, which in extreme cases may originate hallucinations of gross amours being carried on in the patient's presence

It sometimes happens that the alcoholic may have grounds for suspicion in facts, but this *does not* lessen the delusional origin of his accusations A frequent outcome of the *notorious* marital unhappiness thus caused is a brutal wife murder, the body of the victim sometimes being found hacked to *pieces or* partly destroyed by fire. The insane fiend may make but a stupid attempt to escape, or none at all, either expressing surprise at, or doubt of the reality of the event or attempting justification in explanations

The memory and intelligence suffer gravely, though not always obviously, for it may require considerable familiarity with the former peculiarities of the patient to determine the degree of mental impairment, and comparisons of his past and present are often possible only when he has been under observation for a greater or lesser period, in some cases months may be necessary He may be able to attend to routine duties, but is inconstant and easily diverted The reasoning powers are lessened in varying degrees, and many such changes are not determinable off-hand

Delusions, particularly such as relate to the wife's unfaithfulness, are fixed, but not systematized, for his explanations concerning them are vague and illogical There is a melancholic persecutory tinge to all his ideas

Some cases of chronic alcoholism on the verge of chronic alcoholic insanity experience auditory hallucinations of mandatory and accusatory kinds, and these may become so distressing as to lead to suicide, homicide, or insane acts generally The dangerous character of insanity with auditory hallucinations is fully recognized by alienists

In asylums for the insane will be found many cases of insanity that have been complicated with alcoholism, particularly a peculiar form called traumatic insanity, the result of head injuries, after the receipt of which there is a remarkable tendency to drink to excess, and the alcoholism may be combined with the traumatic insanity in every conceivable degree, sometimes outrunning the original psychosis in its influence for evil Epileptics are sometimes incorrigible drunkards, and epilepsy may appear for the first time when an alcoholic has abstained from liquor for some unusual length of time In such cases there may have existed petit mal, unnoticed previously, or even convulsions may have occurred at night, during sleep, and after stopping the use of liquor the fits have appeared during the day, through the alterations in habits Any other form of insanity may have, to some degree, the impress of alcoholism to modify it, and where this complication is extreme, as it is frequently in the head injury cases mentioned (sunstroke victims fall into this category), there are characteristics in common with those of chronic alcoholic insanity that are well recognized by asylum physicians and that often cause considerable annoyance

Soon after the commitment of a chronic alcoholic insane case to the asylum or hospital, he appears to improve remarkably, if he escape the consequences of his last debauch and does not die of pneumonia or exhaustion, locked up at first in a ward, he is sooner or later trusted about the grounds and can be made very useful as a workman of some sort He may refrain from asking for a discharge for a long while for the purpose of convincing the superintendent of his recovery, but unless the patient conceal his delusions, as many insane do, he is liable, with a little questioning or in his letters to friends or relatives, to reveal the permanency of his delusions of persecution The writings of some of these apparently sane alcoholics contain the foulest abuse of mother, wife or children, without the least warrant for it in their former treatment of the patient

Sometimes a weak minded relative may be found espousing the cause of the "unjustly detained" alcoholic, or well-meaning but misguided friends may satisfy themselves of the "recovery," and even resort to habeas corpus proceedings to secure the patient's discharge

Under the watch and restraint of hospital sojourn and their gradual admission to parole, with occasional breaks thereof, many of these patients assume, to all appearances, their original mental condition To the superficial observer they are perfectly sane, many work cheerfully in the shops and talk quite intelligently about the possibility of relapses if allowed to go But a large percentage are importunate, and these are the least to be trusted, for their anxiety to flit is born of their inability to gauge their feeble will power to resist temptation If they are discharged, back they come, not infrequently with newspaper and other criticism of the hospital authorities for having liberated such a dangerous character These same critics are just as liable to write up sensational comments on the injustice of keeping perfectly sane persons at the behest of relatives who, the critics affirm, have some pecuniary motive in the patient's being deprived of liberty Nor is the trouble taken to inquire whether the county is charged with the case as a pauper or not.

When habeas corpus proceedings are begun, the natural inference is that there must be some malign reason for the detention Probably it is just as well in the long run that the public should be suspicious, but the conscientious hospital physicians are put to unnecessary trouble in explaining matters of pathology and general medical experience to laymen who are much more familiar with business affairs

The hospital physicians will congratulate themselves that cases of this kind are improving, and discuss the advisability of trusting them on parole, preliminary to letting them go home on trial, but the records of the cases suggest caution, such as domestic horrors, including attempted wife murder, brutality to children, improvidence to a criminal degree, the wife usually faring the worst, though when he is not drinking she claims her husband to be the "best and kindest of men"

Notwithstanding all this, such near relatives often beset those in charge of the hospitals to liberate their husbands, sons or fathers, poor ignorant creatures, because they can only see the hopeful side of matters for themselves, and can not appreciate the vast fund of information possessed by the doctors as to the frequently disastrous consequences of too early discharges, or, sometimes, any discharge at all

The alcoholic insane have been apparently sane while at the asylum, and even after ten years' trial when they were allowed to return home they would resume all their bad habits, such as furniture smashing, chasing the family into the streets with axes or knives, and after being returned to the asylum in a maniacal state they would resume all their apparent sanity and sweetness of disposition, which arouse the suspicion of the visitor that some unworthy motive on the part of somebody withholds so useful a person from society at large

Among the sadly comic instances of this kind appear liberations after carefully weighing probabilities and enduring the threats, entreaties and promises of the family and the patient, against the better judgment and misgivings of the physicians, and when something does occur from the risk, as too often happens, forthwith not only the public but the relatives censure the weakness of the doctors for having listened to them at all

A washerwoman, who had about as much experience with the inner life of a large city as some physicians acquire, used to dub the defects produced by alcoholism as "street angels and home devils" Much danger to the community exists in the seeming sanity of such cases There is no provision for their incarceration on the ground of their great liability to be homicidal, and when they do commit a murder it is a difficult matter for the public to comprehend the insanity during the quiet stage induced by imprisonment and liquor deprivation

Alcoholic dementia is simply a secondary or terminal dementia of profound type, that has usually supervened upon alcoholism, the intermediate stage of chronic insanity being often short, or having escaped notice altogether, as such, being merged from the general alcoholism It is as permanent and incurable as any other secondary dementia The organic brain and blood vessel changes in this, and other chronic alcoholic insane states often shorten the lives of patients, many succumb from pneumonia which proves so fatal to drunkards generally

Post-alcoholic conditions are such as become evident during abstinence after the protracted use of liquor

If the shock of abstinence is rallied from, we can then determine how much is left of the patient Destructive changes in the brain may be, to an extent, masked by drinking, that is, the behavior of the patient may be erroneously ascribed to the drinking when it in larger part may be due to brain alterations produced by over-indulgence

The extreme ground is taken that by whatsoever means recovery from habitual drunkenness is made, the health is never regained Dr Clum (*Quarterly Journal of Inebriety*, October, 1891, 382), observes that those who have been addicted to the excessive use of alcoholic beverages for a number of years may be restored to a state of sobriety but they are generally left with an entail of chronic disease which eventually ends their career They die temperance men, but die as a result of disease contracted by the excessive use of liquor The habit is abandoned and nature and remedies are given a chance to do their part toward reinstating the individual, but the vital organs have been injured beyond reparation

This gloomy outlook for the "reformed" inebriate concerns a large percentage of cases, but is far from being universal Drunkenness is not the only consideration, the health previous to and during the addiction should be regarded, aside from, as well as with, the drinking habit and its extent, the age, associations and conditions, such as exposure and immoral practices, as incidental or consequential matters, need consideration in ascertaining how far a breakdown is ascribable to drink or its stoppage

Heart weakness that had previously been compensated to some extent by stimulants, whether created by their use or not, often becomes apparent in post-alcoholic life Syphilis is known to have become modified and somewhat checked through the alcoholic poison acting upon the syphilitic poison, and when this antagonism ceases the syphilis has become more virulent Livers, kidneys nerves and brains that have been structurally degraded can not be restored by mere change of habit, indeed, paralytic states may become evident immediately after liquor withdrawal through the shock of readjustment to new vascular workings For example, when an alcoholic neuritis with membrane thickening and beginning spinal cord myelitis has been inaugurated through alcoholism, the sudden change in the circulation caused by abstinence will inevitably render the physical consequences of such inflammatory and neoplastic states more apparent *Pressure symptoms, debility, and marked* sensory and motor impairment are liable to occur, from monoplegias to complete paraplegia

Tremens begins during the abstinence of drinkers, and from circulation changes in the brain, temporary sobriety causes a dazed, bewildered mental state in the hard drinker Even were the craving destroyed, and were the will power to resist drinking to be imparted, by any means, too often the inebriate then finds himself so completely out of his environment, so changed are inner to outer relations as to what constituted his previous existence that he rushes back to his former habits about as a fish would take to water, and for analogous reasons

Hard drinkers are the first to succumb to epidemics, such as cholera and yellow fever, and abstinence merely uncovers the debased organic weaknesses that these epidemics coöperated with destructively

After prolonged use of liquor, abstinence sometimes is followed by acute melancholia in which the delusions of that psychosis are commingled with some that are peculiar to alcoholic insanity This depressed state seems to be owing to exhaustion of the system habituated to alcoholic sustenance, and not yet readjusted to the assimilation of proper food

A demented condition more or less profound may set in from the same causes A well-known stockyards millionaire of Chicago had, up to his sixtieth year, guzzled fusel oil in all its disguises as ethyl alcohol compounds, and a sharper shrewder person was hard to find, but he abandoned his drinking suddenly, utterly and completely, and during the succeeding three or four years gradually became incapable of attending to business, presenting the apathy, memory loss and other characteristics of what was known as "primary mental deterioration" but which Voisin claims to be "atheromatous insanity," the blood vessel destruction found post-mortem justifying the designation While this mental malady is often independent of alcoholic habits, its appearance as apparently connected with the stoppage of drinking is worth noting In those who indulge many years and then quit drinking, the alteration in behavior is quite observable, they are certainly quieter, calmer, and while doubtless far better off than when stimulating, the general tone is below what it used to be, or what it would have been had they not drank at all, meddling with fire must be at the expense of some scars While atheromatous insanity may occur in the temperate, a condition like it, if not identical with it, could readily be conceived as consequent upon abstinence after long addiction, or the pathologic condition mentioned itself could be directly induced by alcohol, and persist, whether alcohol is or is not taken after the condition is instituted The tendency to steatosis in the intemperate can be recalled in this connection and doubtless many cases of so-called dementia from abuse of alcohol may be found to be of Voisin's type of atheromatous insanity

The hyperemic state of chronic alcoholism necessarily alters the cerebral circulation in various ways in many, but not in all cases, causing endarteritis, leucocytic exudation, neoplastic organization and capillary extravasation into the cerebral tissues comparable to the rosacea observable in some drunkards' cheeks and noses In my autopsies of the alcoholic insane at the county asylum, I invariably noticed a rusty discoloration of the dura mater along the course of the superior longitudinal sinus, and other evidences of old inflammatory conditions such as adhesions of the membranes and cerebral tissue of the convexity and basilar regions The vascular and meningeal alterations varied in degree according to the patient's age Where frailty of blood vessel organization existed congenitally there was greater liability to pathologic change in such cases

The finer mental coordinations in any one are maintained by effort, being the latest faculties acquired, and their tenure being so dependent upon full brain integrity, it is plain that the moral nature has been superimposed upon the less easily destroyed brute nature, through finer and weaker histologic arrangements acquired and inherited, demanding for their exercise the clearest kind of brain activity Vitiated blood quickly blots out these better but feebler functions for the time being, just as exhaustion is felt first in our weakest joints So the moral nature, which is merely a higher intelligence, may depart when the seat of intellect is weakened by any cause such as senility, drinking, insanity, arrest of development, traumatism and some diseases

When certain pathologic adjustments, involving imperfect compensations, occur, such as thickened arterial walls which resist the increased flow of blood, then a new plane of mental operation is established, which, if disturbed by change of habits, as by withdrawal of the customary greater heart impulse, it is but partially and inadequately recompensated by the pure blood Practically, the adjacent cerebral tissue must suffer from anemia to a greater or lesser extent, and where previously the blood was driven through disarranged avenues, it now makes its way feebly and in places not at all Nor is this all, the sclerosed and otherwise changed tissue becomes a more prominent hindrance to function when the artificial nutrition and circulation is cut off So the poor fool of a drunkard is too often thus "damned if he does, and damned if he don't" continue

Summarizing post-alcoholic bodily and mental states there may be found many organic destructive changes in the blood vessels, liver, nerves and brain, which were not so evident during the addiction, owing to the somewhat compensatory effect of the alcohol, and hence the masking of diseases

The simple privation may kill through the weak heart losing its wonted stimulant, but such cases are not very common, debility is the most frequent consequence of "reform," but this is often a return to what preceded and may have led to the over-indulgence Cerebral blood vessels subjected to engorgement are liable to rupture at any time where weak points exist, and fatty degeneration of vessel walls, induced by the liquor, may culminate in apoplexy, whether drinking is continued or not

A single severe attack of delirium tremens may make profound changes for the worse in the future workings of the brain, and the typhoid stage of some cases of delirium tremens show the ravages of the poison often in life-long sequelæ

Chronic alcoholic insanity may make its first gross appearance after abstinence enforced in jail or otherwise

Necessarily, when liquor is withdrawn, a change for the better is ordinarily the rule, but such withdrawal in some cases may operate as a shock, and in all cases a readjustment of the entire physiologic make up must occur It is conceivable that epilepsy or insanity may find in such shock a potent exciting cause and the whisky soaking is ample as a predisposing influence, when it can alter the brain structure, in time, as thoroughly as a contusion or a concussion

But what the inebriate has drank, how long he has been drinking, and his power of resistance, associated diseases, hereditary and other tendencies, are to be taken into account, and with these it is surprising how large a number of heavy drinkers escape any obvious trouble due to such excesses A well-known druggist of Chicago was a sot until his fortieth year, stopped drinking and died at 70 years, having built up a large business, while others who had not taken half his risks with liquor succumbed during or after ceasing their bad habits

Post-alcoholic conditions such as insanity, paralyses, weak heart, etc, that occur in a minority of cases after alcoholic disuse, only the most thoughtless or perverted could use as arguments against the stopping of drink, as the liquor in such cases produced the trouble which merely culminated after the habits were changed, such climax, being inevitable in any case, and impending, might have been reached earlier, or in a graver form, had the inebriety continued

In a few words, drunkenness is a constant menace to the mental and bodily health, and it is far safer to escape from its ravages, scarred and maimed, than to go on sooner or later to certain destruction Though the vast majority may be rescued entire, or nearly so from intemperance, no one can tell what the chemic devil has left of him until months or years of sobriety have passed

---

THE ESSENTIAL OF INSANITY

BY J SANDERSON CHRISTISON, M D
FORMERLY OF THE NEW YORK CITY ASYLUMS FOR THE INSANE, BLACK WELL'S ISLAND AND WARD S ISLAND
CHICAGO

If by insanity we simply mean more or less deviation from the free normal action of the mind, without regard to cause, then, indeed, no mortal is constantly free from it For as mental activity, in degree and range, is a measure of physical tone and proportion, especially of the brain, it is quite evident the accidents of existence preclude a constant normal But the term insanity, to the popular mind implies the state of personal irresponsibility and the question in regard to a particular act, is the proof of the existence of this state The law, with reference to a specific act, simply demands, Was he sane or was he not? implying by the question either a fracture of mental integrity or a degree of derangement beyond which responsibility justly ceases

It is quite clear that from a practical standpoint, we can not hold to the position that all men are insane or that all abnormal states of the mind are degrees of insanity, though leading to it Just as we do not recognize tuberculosis until the bacillus is in the field, so we may have an essential characteristic of insanity That essential of insanity is a delusion uninfluenced by evidence sufficient to refute and due to disease of the brain. This definition includes a much wider range than asylum wards and embraces a class to whom we might hesitate to impute the charge, while it drops others into the still wider circle of cranks and crippled creatures. But to maintain that a man is not really a lunatic unless he holds a delusion will depend upon what we regard a delusion to be. An insane delusion is a false concept—an idea which is the product of defective data and defective reasoning and held in spite of the presentation of a corrected data and corrected reasoning. This distinguishes it from a common delusion—an error of belief remediable by suitably put evidence.

A common or simple delusion is due more to educational *errors*, but which by *necessity*—from the aberrant nature of errors—they more or less induce material conditions off the normal line, and thus, in addition to the direct evil of their falsity, they indirectly conduce to undermine the physical tone requisite for perfectly free mental action. But the lesser degree of defect may be in the course of the evolution, of the greater, yet so common is it that few of us could plead freedom from a finding of some sort.

Insanity has no direct relationship to the size or shape of the brain, but only to its lack of tone or integrity—a molecular disintegration—which in its last analysis is the registration of conduct and which ought to be in line with a motive consistent with common sense—the normal product of common experience. *A simple error of belief*, a mere notion or faint suspicion, may so mislead as to react injuriously before correction is made, or they may even become the substructure of a slowly constructed system of beliefs having a degree of plausibility which may earn for its advocate a respectful attention. As one error held begets another, and as all errors, when actuating, mislead in conduct which determines the tone of the organs of mind, it is evident the result of the one becomes a cause of the other, and thus we may have insidiously developed a fixed delusion or systematized set as in a Swedenborg or a Schweinfurth. If the tone of the brain is fully at par, the action of the mind will be accurate as far as attention is directed both as regards the nature, number and order of perceptions or sensations and the process of reasoning on their relationship and thus correct conception result. It will be the truth, if not the whole truth. A greater brain and one more perfectly proportioned would supply the energy, other things being equal, for more extended attention, and thereby a more comprehensive result.

Systematic observations in prison and asylum practice in New York city abundantly satisfied me that neither mere shape nor size of brain had any thing to do with insanity or criminality. But it was evident that the causative conditions of shape and size did have to do with capacities or talents which, did they not meet a fitting environment, would at least negatively contribute to loss of brain tone from the simple lack of proportional exercise, and in this way lead to demoralization, which, of course, always induces disease or a receptivity for it in some degree.

The delusions of illusion and hallucination differ from the purely relational—those wholly due to ideational incompetence—only in being less centric in origin. They are more fleeting and susceptible of correction, but they may be just as strongly actuating while present. Every delusion is an immediate product of defective ideation—the intellectual act involving perception, reason and will and expressing a failure of the brain. When illusion and hallucination are absent, the delusion is purely the product of ideational incoherence—an incompetent relationship of the ideas involved. The faculties are subjective and the emotions are irregular and either excessive or greatly reduced, with egotism, suspicion, jealousy or fear made manifest. These states are always symptomatic of cerebral instability and although so common, they can not exist in the perfect individual who necessarily has a clear conscience and correct appreciation of facts within the range of his vision, which is serene at all times. Their combination and form of associated delusion are formed by the elements in the history of the individual. Great depression or great excitement can not exist without delusion, for the mental condition is such that ideas can not be correctly associated and thus, if the stage of confusion is transcended, some insane delusions arise, although they may only be fleeting. If correct facts in correct form or relationship were present in consciousness, such morbid manifestations could not exist any more than fire can without fuel. Egotism, jealousy, suspicion, hatred, envy, anger and fear are all expressions of morbid condition or weakness, though we regard them in moderation as perfectly natural. They are due to imperfect comprehension of facts before the mind and which is a measure of lost energy. In delusion, the faculty of attention is so weakened that the presentation of the truth is not appreciated.

The emotions are the product of subconscious ideational activity, made conscious in the form of feeling instead of image, and their precise disposition will accord with the data of the memory—the purely conservative faculty—but only those data which are in affinity with the exciting agent. Emotion is inversely proportionate to intellectual range and is the expression of the inability of the intellect to take distinct and immediate cognizance of all the ideas in the memory aroused by the excitant, just as it fails to distinctly perceive all sensory impressions from the outside. This is a normal condition, but is very often out of proportion long before derangement to the degree of insanity is reached.

By the free normal action of the mind, I do not mean an everyday type of health, but a much higher. To be on a level with a certain class or race of humanity, may be a long way below the highest possibilities of individual capacity. Indicative of this fact is the common lack of quickness, preciseness and completeness of mental action within the range of individual knowledge and capacity. Our criterion should be formed from ultimate motives for existence. Insanity is not a relative term, but a positive. It is an extreme aberration from the normal, and the normal is only normal in so far as it is in correct line with evolution or final purpose in nature and not simply in harmony with immediate social environment.

An insane delusion has three components, error of fact, incapacity for correction, error of inference and illogical tenacity. The responsible faculty for this is the attention which is so affected by a weakened will that it can not be held long enough to complete perception and conception, and ideational displacement results But as the will is the dominant power of the mind and owes its strength to support from the other faculties, it is evident that its weakness is due to a general loss of energy, which subserves the mind as a whole, and as a consequence thus becomes an added cause for farther evil

The evidence of a delusion is not always readily recognized, even by asylum physicians Some subjects secrete their delusions, some have their delusions instantly dissipated by the presence of a physician, officer or stranger, some only have momentary delusions or perhaps frequently changed, some change with prominent events, some have delusions so buried that they can only be elicited by particular conditions and requiring the analytical skill of an expert

But the point of present issue is that where there is no delusion, there is no insanity, for the mind that is competent to comprehend facts and their bearings within the scope of its education and the limits of ordinary surroundings is a mind capable of correction on any error, and, conversely, a mind that is not thus competent must of necessity beget delusion of one form or another which it is as incompetent to discharge, no matter what the evidence combating

---

FURTHER REPORT OF THE SERUMTHERAPY IN TUBERCULOSIS

BY PAUL PAQUIN, M D

PHYSICIAN IN CHIEF ST LOUIS SANITARIUM FOR THROAT AND LUNG DISEASES

ST LOUIS, MO

Up to this date all of the reports which I have had the honor to make to the medical profession, bearing on the use of the horse-blood serum in the treatment of tuberculosis, cover a number of cases in which the improvement had been more or less marked Our experiments up to the last report had not gone far enough to justify the statement that we had, in fact, cases of tuberculosis which had been cured The present writing is chiefly for the purpose of reporting results of a more positive nature and, at the same time, to say a few words on the complications that may arise during serum injections, the conditions which militate against its use, also the extent, so far as I am able to present from past experience, of the expectations that may be based on the new treatment I will begin with the latter propositions

In the first place, one should always bear in mind that tuberculosis varies a great deal with individuals and with respect to the organs affected Pulmonary tuberculosis itself presents a wide range of pathologic conditions that must be judged and interpreted according to the extent and nature of each, locally and generally on the system Consequently, no two cases of pulmonary consumption can, with safety, and hope of success, be treated alike by any one remedy, irrespective of the general and local constitutional or organ disturbances One would suppose that a specific treatment should apply to all forms of it. One would think that if creasote is good in one case it ought to be in another If inhalation of essential oils does good in one case it should benefit in another If serum injections produce good results in a given case, they should have similar effects, irrespective of any other treatment, in any case, affecting any organ

But such is not the case It is unfortunate that so many seem to think that with a given specific remedy for any given disease, all that is necessary is to apply that remedy mechanically, without respect to anything else, physiologic or pathologic Chronic tuberculosis of the lungs may consist of scattered tubercles throughout one or both lungs (and hundreds of them), each surrounded by a special envelope, impenetrable by the circulation or by medicines These tubercles may be surrounded by acute inflammatory processes or free from them Some may be in an advanced stage and others just forming In such cases, the opening of the tubercles happens gradually and successively, that is, some of them break to day and others to-morrow or later on Consequently, a more or less constant process of eruption goes on for months or years Sometimes eventually, cavities are formed, during which certain principles of the morbid matter are partly absorbed, but mostly expelled by expectoration It is evident that no form of treatment can arrest these slow cases promptly The good results of serumtherapy in these have been slow in proportion to the nature of the affection, but have occurred, and we have under observation patients of this class who are unquestionably steadily improving, if we are to judge by the disappearance of the chief symptoms, such as night sweats, fever, loss of appetite, emaciation Indeed, to arrest the progress of the disease in such cases is itself progress toward a cure In another form of tuberculosis, one may meet with contracted lungs, sometimes with alterations of a more or less fibrous character, lungs encased usually in a narrow or otherwise defective chest These cases are also very slow (they do not always end with cavities), and serumtherapy as well as other agents must naturally fail to bring quick improvement

It is only slowly that one can reach such pathologic lesions, whatever agent is used

On the other hand, we find chronic cases of tuberculous processes existing here and there, or localized in one apex or both apices, which are of a subacute character, and around which there exists more or less infiltration which, under physical examination, simulate to some degree the fibrous consolidations which I have mentioned before This form of tuberculosis yields more readily to the serumtherapy than those above mentioned

Again, there are cases of chronic tuberculosis of the lungs in which the tuberculous alterations consist first in localized inflammatory processes, unknown sometimes to the individual until a hemorrhage takes place and which sometimes end in cavities more or less extensive, and more or less serious according to their location, etc One occasionally meets with such cases without detecting any other alterations in the lungs

It must be apparent to any physician that the various conditions just mentioned (which do not by any means cover all the types of pulmonary phthisis) are not to be treated by any stereotyped formula and serotherapy, acting as a specific agent, should not be depended upon exclusively, irrespective of other conditions in the diseased organization In other words, every case should be managed scientifically, using the serum only for the purpose it is intended, namely, to give to the organism the physiologic elements which it lacks to fight the tuberculous process from within

Most of the chronic forms are mixed infections, and therefore demand additional treatment, and were they not such, accessory therapy is certainly in order to meet any special condition, and physicians should not neglect them under any circumstances In our first reports we made it a point to explain that all our experimental cases had been treated exclusively with serum Exclusive serumtherapy was necessary in those experiments, because we had to demonstrate as far as possible what the serum alone could do, but we are not justified in this early stage of the serumtherapy to lay aside everything else that may be useful to meet any special phase of disorders in a tuberculous individual In fact, it is unscientific to treat diseases by any stereotyped method Each case of any given disease should be considered on its merits if I may so speak, and after proper consideration one should use the most potent or most specific therapy and add to it, if necessary, according to what the symptoms may suggest

We have beside to deal with acute forms of tuberculosis which, under ordinary treatment, may be classed as hopeless from the very beginning It may be said that they always end in death Medicine of the past shows no autnentic records of cures in any such case It is in these, however, that serumtherapy has proved its efficacy most strikingly It is only within the last three months that we have had opportunities of testing the serum in this form of the disease and, already, I am in position to point to three patients in which the diagnosis made microscopically and physically was unmistakable, who have arisen from a bed of sickness where everything pointed to death within a short time These cases, were not in my own practice, and, consequently, I am not at liberty at present to give their history But I will mention that I have seen two of them, and that I have verified the microscopic analyses previously made in them and know that both of them had acute tuberculosis of the lungs in the worst form and both are now entirely free from bacilli, and are up and about and gaining strength, and one has absolutely no physical or microscopic sign of the disease left This one, a young lady of about 18 years, had been at the time of the beginning of the treatment, prostrated in bed some four or five weeks, had had a temperature of 104 to 105 during three weeks preceding the injections, had had cerebral symptoms to the degree of absolute loss of mind during all that time, had both lungs so seriously involved that breathing was painfully short and laborious, emaciation and weakness were so pronounced that she was absolutely unable to raise her head, and could barely lift her hand She was treated about three weeks with the serum and the temperature went down steadily after about four days from 105 to 98 5, the lungs gradually but steadily cleared up, hemoptysis and expectoration ceased, the bacilli entirely disappeared, the clouds were lifted from the mind, the appetite returned and the young lady is out of bed, up and around, and putting on flesh rapidly This is the most striking result we have obtained by the *exclusive* use of the serum The physician in charge, who will report the case himself shortly, excluded all other medicines because the case, after consultation with other physicians, was considered hopeless by any of the old modes of therapy The serum was used as the last resort without any hope whatever

The other patient of the two just mentioned, whom I have seen, was an old gentleman who had also been prostrated in bed several weeks with acute tuberculosis diagnosed as such by some of the most eminent physicians of St Louis, who, after consultation, considered his case hopeless This patient began the serumtherapy under another physician, and within six weeks, I believe, was also raised from his bed and is out and about Not a bacillus is to be found in his expectoration to-day, one lung is entirely cleared, but in the other there remain some adhesions, which will probably remain, as they seem to be of a fibrous character Certainly the tuberculous phenomena seem to have been arrested, the germs are there no more, and the ravages which they have produced are being healed[1] We have also two cases of chronic tuberculosis without any more symptoms of the disease except the evidence of the cicatrix They were both bedridden and are now both working hard every day

Now as to the complications that may arise in acute tuberculosis by injections of serum, I will mention first the general disturbances Constant injections of serum may result in rheumatic symptoms, particularly in those with rheumatic diathesis Swelling and pain of the articulations and pain in the muscles may arise By suspending injections and using lithia the symptoms disappear Occasionally urticaria results, scattered over the skin around the ankles, body, neck, etc A curious accident that occurs sometimes is a sudden disturbance of the circulation, evidenced by a very pronounced flushing of the face, a condition which usually promptly disappears This occurs during injections or just after The face becomes gorged with blood, the patient feels dizzy and will fall if not assisted to lie down These symptoms appear and disappear within two to five minutes, in my experience Two or three times, after such occurrences, there resulted a chill and occasionally a headache, and pain appeared in the spinal column In no instance, except one, did the heart suffer during the trouble In this case it became very feeble and hypodermic injections of stimulants (whisky and nitro glycerin) were deemed useful to assist recuperation This disturbance of the circulation occurred in my practice and my experiments eight times in a total of some eight thousand injections Whether it can be fatal or not, I am unable to say, but it is so rare that it is not to be considered in any worse light than any untoward symptom that may arise from the administering of any other medicine of a potent character which we use daily in medical practice, such as cocain, sulfonal and numerous other medicinal agents which the readers will readily recall to memory

With respect to the kidney's action, I have to mention that in two cases in which there existed already a trace of albumin, albuminuria increased without, however, producing any of the serious symptoms that we note in Bright's disease In neither of these cases were there any casts to be found In another case, which was not directly under my control, and which unfortunately had not been analyzed before beginning the injections, albumin was found in great quantities after the patient had been treated two or three weeks I am unable to say whether this came from the injections or not, inasmuch as it occurs frequently enough, that albuminuria exists with tuberculosis On this point, I will mention that, being in the habit of analyzing the urine of every case of tuberculosis before treatment, I have found the last four months, six cases of albuminuria in thirty-two cases of pulmonary consumption

---

[1] This old gentleman patient now weighs nearly 200 pounds Weight at beginning of treatment less than 160

From the foregoing, I judge that it is not wise to use the serum in cases where there is kidney inactivity Locally, the serum injections may produce erythema and local irritations more or less pronounced These are sometimes sufficient to produce an elevation of temperature and they should be treated according to their nature It would seem from the foregoing, that serum injections in tuberculosis, or in any other disease for that matter, should not be considered entirely free from possible complications, and that every case treated should first be thoroughly analyzed and treated on its merits With respect to the results of the serum in the hands of others, I am pleased to say that I am getting daily excellent reports which will serve materially in deciphering the conditions in which the serum will or will not act beneficially or will be too slow for practical purposes I have now in my hands, reports covering the use of the serum in various parts of the country in many different tuberculous conditions from which I shall glean material for an article explaining various kinds of results All these, I can now state conscientiously, give evidence that the principle of serotherapy in consumption is correctly interpreted in our experiments and our judgment as made known by our reports In New Orleans, California, Missouri, Illinois, etc , we have had excellent results, and, naturally a percentage of failures

Before closing, I wish to state that in local tuberculosis of the skin, glands, and surgical cases with fistulæ, with and without operations, the results have been positively beneficial Specific reports will be given by the physicians who have undertaken such cases in this city and elsewhere Cures have practically occurred

In conclusion, I beg to warn the over-anxious against the idea that a few weeks of treatment of any case of chronic tuberculosis will effect a cure The cases we can now report as free from tuberculous symptoms and which were in the first and second stages of the disease have been treated not less than four to six months steadily Four to ten months of steady treatment should be contemplated from the onset No miraculous or magic effects should be expected by any doctor or patient Considering that tuberculosis is fatal in 99 per cent of cases, and generally very slow, this conclusion is entirely reasonable

---

SOCIETY PROCEEDINGS

American Public Health Association.

Proceedings of the Twenty-Third Annual Meeting held in Denver, Colo , Oct 1-4, 1895

SECOND DAY—WEDNESDAY, OCTOBER 2

(Continued from p 632)

The Association reconvened at 10 o'clock, A M, in the Brown Palace Hotel, with PRESIDENT BAILEY presiding

There was a larger attendance than during the preceding day's sessions, as a number of delegates had arrived since last adjournment

CHAIRMAN SEWALL, of the Local Committee of Arrangements made announcements regarding various trips, excursion rates to same, social functions, etc

The Executive Committee, through Secretary Watson, recommended that the names of the applicants in his hands be elected to membership Upon motion duly seconded th Secretary cast the ballot of the Association for them

The Committee also recommended the adoption of th resolutions offered at Tuesday morning's session by Dr Mitchell, regarding the transmission through the mails o bacteriologic specimens when properly prepared so that n danger could possibly accrue to those handling the packages etc Dr Mitchell then exhibited two samples of tubes and cases that he had devised for this purpose which he had proved was perfectly safe to send specimens in, and deemed to be absolutely safe to admit through the mails

The resolutions were then unanimously adopted The committee also recommended that the committee on the centennial celebration of the discovery of vaccination be restored by the Association Adopted

The committee recommended the creation of a new committee, namely, a Committee on Forestry and its Relation to Public Health Adopted

After some additional routine business had been disposed of, Treasurer Henry D Holton, of Brattleboro, Vt , submitted his annual report which showed receipts from September, 1894, to date from all sources to be $3,627, and disbursements as per fourteen vouchers , that there is remaining in the treasury $493 98, *Index* fund unexpended Upon motion, the report was received and referred to an auditing committee consisting of Mr Crosby Gray, Dr H B Horlbeck, and Dr J N McCormack

DR C N HEWITT introduced the following resolution on the death of M Louis Pasteur, which was duly seconded

Resolved, That this Association has heard with profound sorrow of the death of Louis Pasteur That it offers to his family, to his assistants at the Institute Pasteur, to his country, to the members of the profession, sincere condolence in the loss of a master of science His work for the alleviation of human suffering is as he would have chosen—his everlasting monument His example as an humble and attentive servant and student of nature, is the precious legacy he has left us

On motion of Dr McCormack, a silent rising vote was taken In addition to the foregoing, upon motion of Dr Formento, a cablegram was sent to Dr Roux, collaborateur to Pasteur, containing these words "The American Public Health Association mourns the loss of Pasteur"

The roll of the Advisory Council was called, and the following members were present

Colorado—Dr Henry Sewall, Denver
Connecticut—Dr R S Goodwin, Thomaston
Delaware—W C R Calquohoven, Wilmington
Illinois—Dr Liston H Montgomery, Chicago
Indiana—Dr L S Whitesides, Franklin
Iowa—Dr A W Cantwell, Davenport
Kansas, Dr Daniel C Jones
Kentucky—Dr J N McCormack, Bowling Green
Louisiana—Dr Felix Formento, New Orleans
Maine—Dr A G Young, Augusta
Maryland—Dr James F McShane Baltimore
Massachusetts—Dr S H Durgin, Boston
Michigan—Dr Cressy L Wilbur, Lansing
Minnesota—Dr C N Hewitt, Minneapolis
New Hampshire—Dr Granite P Conn, Concord
New Jersey—Dr Henry Mitchell, Asbury Park
New Mexico—Dr S D Swope, Deming
New York—Dr A W Suiter, Herkimer
North Carolina—Dr R H Lewis, Raleigh
North Dakota—Dr John Montgomery
Ohio—Dr Charles O Probst, Columbus
Pennsylvania—Crosby Gray, Pittsburg
Rhode Island—Dr Gardner T Swartz, Providence
South Carolina—Dr H B Horlbeck, Charleston
Tennessee—Dr W C Bailey, Knoxville
Vermont—Dr H D Holton, Brattleboro
Wisconsin—Dr U O B Wingate, Milwaukee
District of Columbia—Dr Ralph Walsh, Washington
U S Army—Deputy Surgeon-General A H Woodhull, Denver, Colo
U S M -H Service—Surgeon P H Bailhache, New York
U S Navy—Surgeon Bates, New York
Dominion of Canada—Dr F Montizambert, Quebec
Province of Ontario—Dr Peter H Bryce, Toronto
Province of Quebec—Dr E P La Chapelle, Montreal
Manitoba—Dr James Patterson, Winnipeg
New Brunswick—Dr George E Coulthard, Fredericton

The appointment of Mexican members to the Council was deferred until the arrival of the delegates from the Republic

DR H B HORLBECK, Health Officer of Charleston, S C , read the first paper which was a brief one, entitled "Municipal Steam Disinfection " The author illustrated his remarks by lines and drawings upon blue paper

The succeeding essay was practically upon the same topic, "*Disinfection in American Cities*," by Dr Charles V Chapin, of Providence, R I

Both papers elicited marked attention and contained much valuable information concerning the methods of various cities throughout the United States Dr Horlbeck thinks that Charleston has the best steam disinfecting system in this country The use of steam and a solution of bichlorid of mercury was recommended where contagious diseases were prevalent Dr Chapin's remarks were more extended The statistics he presented were gathered from fifty cities in this country and Canada Only two out of this number disinfect after measles and the other minor contagious diseases These are Rochester and Toledo, and their, systems are very thorough New York, Brooklyn and Philadelphia were mentioned as devoting particular attention to the spread of phthisis In Detroit, Denver and Newark, the favorite method of fumigation is with sulphur St Louis uses steam, and several other cities use mercuric bichlorid

Mr George J Kindel, of Denver, was accorded the privileges of the Association He is a manufacturer of bedding supplies, mattresses, etc , and dumped on the floor a collection of shoddy rags, not very clean in appearance, which he stated in a vigorous manner was a fair sample of the sort of material put into rag mattresses of the cheaper quality He thought it was dangerous and quite likely to breed disease He asked the Association to investigate the manufacture of such bedding, and concluded by saying

"For years I have earnestly endeavored to bring about reform in the manufacturing of bedding In the interest of pure and healthy bedding, I, three years ago, visited the health authorities of the cities of Chicago, St Louis, Cincinnati Buffalo and New York city Also those of Liverpool and London, England

"Near New York city is manufactured to day, a shoddy (rag) comforter that is sold in every city in the United States Shoddy (rag) mattresses are manufactured in every city of 100 000 inhabitants In our beautiful city of Denver, there are two such manufactories, my own, and that of Kent & Stuchfield It is not by choice, but by compulsion that they are made here Chicago, Omaha, Lincoln and Wichita ship them in by the carload, hence we must make them or go out of the bedding business, as in this section four-fifths of the bedding is made of this vile stuff

"In addition to the notice of this subject to the State Board of Health, I have again called the attention of our estemed Board of Health to this subject while a member of the grand jury in April, 1894, when I endeavored to indict myself for making this dangerous bed filling We had these medical officers before us to give expert testimony They differed widely Some went so far as to say that there was nothing unhealthy or dangerous about it Needless to say, the grand jury did nothing, except to make a slight mention in their report to the court about it

"So long as there is no national law governing the subject, just so long will these goods be manufactured and sold under the innocent title of wool bedding Every drygoods and house furnishing goods store have these goods on their counters

"The following extract from a Chicago paper may be read with interest It furnishes a good example of the old truth that an ounce of prevention is better than a pound of cure What precautions have we in the matter of the old rags? None, and it is an enemy tenfold greater to the public than the mails could be

Orient Mail to be Fumigated —*Passengers landed from the Galic after being inspected* —San Francisco Sept 20 —The steamer *Galic*, which arrived this morning from Hong Kong and Yokohama did not stop at Honolulu She brought eleven passengers from Hiogo the worst infected port in the Orient. No sickness was reported on the trip across and no alarm was felt by the ship s officers Since last advices there has been an increase of the cholera plague in the Oriental ports During the two weeks preceding the sailing of the ship there has been 6 deaths from cholera in Hong Kong 51 deaths out of 51 cases at Fagasaki 256 deaths out of 829 cases at Hiogo and 27 cases with 19 deaths at Yokohama. After inspection by members of the Board of Health the passengers and mail was landed, and the steamer returned to quarantine

The postmaster to day received instructions from Washington in response to his suggestion directing him to fumigate all mails received from infected ports

The chief of police to-day ordered a house to house canvass for the purpose of compelling all citizens to put their houses in the best sanitary condition possible

I hope you will take up this matter earnestly, and prevent, at least, one source of contagion

THE MICROSCOPIC DIAGNOSIS OF DIPHTHERIA BY A NEW STAINING METHOD,

was read by Dr H C Crouch, of Denver, member of the *Colorado State Board of Health* The author stated that the diagnosis of diphtheria by the microscopic examination of cover glass preparations from the membrane is admittedly imperfect By the ordinary method, we are obliged to rely upon the occurrence in large numbers, or almost pure cultures of bacilli having certain morphologic peculiarities which, however, are not sufficient to distinguish them from other bacilli found in the mouth, if such are present in any quantity A method which would give a specific stain as with the tubercle bacilli would evidently be of the greatest importance Such a stain has not yet been found Fortunately it is not necessary to have a stain so specific as to detect single diphtheria bacillus, for they are invariably present in a certain quantity, if present at all A method which will detect certain of them with some degree of certainty would be sufficient in most cases, and such a method it seems to me I have found, at least if used with the proper precautions and with sufficient skill I believe from my experience with a large number of cases that this method will suffice to determine the diagnosis in a very large percentage of cases

In conclusion, he said, that the diphtheria bacillus as seen in preparations from cultures consist of bacilli of varying sizes, the larger ones particularly presenting characteristic features in the way of club shaped ends and irregular staining, but all forms showing a tendency to the alteration of deeply and lightly stained portions In addition to this, and distinct from it, are certain round or oval bodies which may be made apparent by certain methods, the existence of which was brought to our attention by Babes, Neitser, and Ernst The method pursued by the latter was to stain strongly with hot methylene blue, and follow this with bismarck brown These bodies would be blue, the rest of the bacillus being brown I have been investigating the feasibility of employing this peculiarity of the diphtheria bacillus to differentiate it from other bacilli found in the mouth, and with a degree of success beyond expectation I found, likewise simpler methods of staining, and peculiarities which I believed have escaped attention hitherto If a fresh serum culture is stained momentarily with a 1 per cent solution of methyl green, it is often possible to bring out these bodies without further treatment Treated thus they have the peculiarity of reddish granules in a faintly green bacillus, usually one at each end By staining with methyl green more strongly and following with methylene blue, bacilli with red dots resembling spores will be seen These bodies have apparently a peculiar affinity for methyl green, with which they enter into a chemic combination resulting in change of color from green to red He had consequently employed methyl green for their detection By adding other colors, the penetration of the methyl green may be increased, and a double stain obtained immediately I found dahlia most useful, employed in the following proportions 1 part of 1 per cent, dahlia water, 5 parts 1 per cent methyl green, and 4 parts water If either color predominates in the stain too decidedly, the other color is cautiously added until the desired result is tested on the bacilli from which a culture is obtained The stain works instantaneously, and if too deep the effect is not obtained In such a case, the cover glass may be treated quickly with bismarck brown, which replaces the dahlia in the body of the bacillus, leaving the bodies described standing out in contrast I have tested this method on a large number of cases during the last six or eight months and have never failed to find the result of the culture positive where I found these forms present in the cover-glass examination In one case where I had diagnosed diphtheria, the first culture was unsuccessful, but the second culture which I had taken, confirmed the diagnosis, which fact it seemed to me, indicated that the direct examination should always have its place in addition to the culture These bodies I do not consider to have any connection with spores in spite of their superficial resemblance They are found in the greatest numbers in young freshly growing cultures and are much less abundant in older cultures They may be readily detected in cultures only a few hours old, and thus made use of to confirm a diagnosis earlier than the full development of the culture That they are not degenerative forms is evident from the same considerations I am inclined to attribute a nuclear nature to them, and propose the name *nucleoid* bodies They are evidently connected with the active growth, and are absent in the resting forms, suggesting thus the resemblance with indirect cell division Being particularly abundant during the earlier and more rapid growth, they are readily found in the earlier stages of the disease, and from the ease with which they may be brought out, they acquire a very great practical importance in the microscopic diagnosis of diphtheria

In the discussion that followed, by Drs Mitchell and Kinyoun, the latter gentleman said among other things, "that all methods are a question of doubt in diagnosis" Other members who discussed the paper and viewed the slides under the microscope were Drs Swartz Chapin, Wright, Shrader, Guilbert, Leal and Montgomery

At 11 45 o'clock the Association adjourned until 2 30 P M

Second Day—Afternoon Session

The Association convened at 2 30 P M with the President in the chair

The first paper announced to be read was by Dr Edward Jackson, of Colorado Springs on

SUGGESTIONS AS TO OCULAR HYGIENE IN THE SCHOOLS

Among other statements, the author said, all schemes for the improvement of the ocular conditions of school rooms failed more or less to take into consideration the necessity of teaching children how to use their eyes The child is not taught to use his eyes, nor is he taught how to avoid eye strain To accomplish this it is necessary to teach the teachers a few things which they usually do not know Much of the work done has been merely in showing the defects existing without showing any remedies Even if it were usual to have examinations made of the eyes of the children, this would not be sufficient If the teachers do not themselves understand the eye they can not teach its proper use The eye itself is not a sufficient monitor, as indicated when eyes are habitually used after they are tired The matter of fair limits of study, and the lighting of rooms should be given careful consideration in every instance The more light the better, so long as the light is not blinding The point of determination should be the darkest part of the room By an arrangement for diffusing and mellowing the brilliant rays, and throwing them into the darker corners, the room can be made satisfactory The relation of floor space to window space does not by any means furnish the proper standard for determining the proper amount of light The conclusions arrived at were

1 The child should be trained in the use of its eyes

2 The supervision of the work in the school room as to the way in which children use their eyes should be constant

3 More care is needed in lighting school rooms

In the discussion, Dr R H Lewis of Raleigh, N C, said one trouble was, that the child was permitted to stoop over his desk He called attention also to the great improvement which the system of vertical writing affords over the old slanting system, which made it impossible for a child to assume a wrong attitude at the desk

Dr James Madison Watson, of Elizabeth, N J, said--the question under consideration is of the utmost importance, and he hoped that there would be some practicable suggestions for future work He emphasized the fact that Nature must be aided in this, as in all things A man walking on a street in a city, gradually learned to see many things at once without appearing to see anything The child must be trained to see many things at once, but not too many Most people see too much, consequently they use the eye too much

Dr H D Holton, spoke of the trouble and danger arising from constantly changing the focus of the eye of the child in school, looking from the blackboard to the book, and back again frequently School directors should investigate this matter and provide against such a danger to children's eyes Distant focus and near focus should be more intermediate when a child has to study simultaneously its book and a blackboard

Dr A G Young stated, that it was more trying to read from the blackboard than from the book, because the range of vision was usually less, the figures were not so plain and the light was often bad He thought there should be great care exercised in this matter

Dr S H Durgin inquired of the essayist, if there had been any examination made by an oculist of the children's eyes He thought there should be an inspection of children in all schools to ascertain their ocular powers, as there is great variety of vision and the same requirements should not be made upon all alike Teachers should learn the peculiar characteristics of each child and always consider them

Dr H M Bracken of Minneapolis, Minn, considered that teachers should be taught enough to discover faults in the eyes of pupils and know which ones should be sent to an oculist for closer examination

Dr James A. Stewart of Baltimore, Md, inquired if a blue board would not be better than a black board—he thought perhaps, black boards are oftentimes too shiny

Dr Jackson closed this interesting discussion He mentioned several methods for teaching children to see quickly and accurately He stated the fact that the illumination should be centered upon the thing looked at and as little as possible upon other things It is very difficult to see figures on a black board because of the polished surface Black board work is also hard on the eyes because of the uncertain amount of reflection of outside light He had purposely kept the number of points in his paper down to the minimum, thinking it would prove more interesting to do so As for the examination of children, he thought it an anomaly that they were questioned so closely concerning their former studies and so little concerning their physical powers, their ability to see, hear, and feel He would not underestimate the advantages of having physical investigation of individual children, for he thought this quite necessary, if not more so than to look after the conditions of all children He thought it was a mistake which surely only needed to be brought to the attention of school directors The system in vogue in examining the eyes of railway employes might be introduced in the schools with good effects Regarding the color of the board he thinks this is of less importance than the reflection of the board If a board, dead black, with no gloss, is secured, it will not injure the eyes

The second paper of the afternoon, was

ON THE OUTLOOK FOR A GENERAL SYSTEM OF REGISTRATION OF VITAL STATISTICS IN THE UNITED STATES,

presented by Dr Cressy L Wilbur, division of vital statistics, State department, Lansing, Mich The Doctor began by quoting a prophecy made at the first meeting of the Association twenty years ago by Dr Elisha Harris, who thought at that time that the United States would have a perfect inter State system of vital statistics before the end of this century He took up the points and showed why it was that this prophetic vision had not been realized, and continued by stating that the dependence of accurate registration of vital statistics upon a certain degree of density of population, was illustrated by the experience of this country and Europe Limits of density of population were suggested below the minor of which accurate registration is practically impossible, and above the major of which such registration naturally goes into effect as an indispensable adjunct of social organization The condition of the United States as a whole was considered with reference to such limits, and the conclusion reached that the advent of a general system of registration for this country is much more remote than many vital statisticians have supposed A review of the actual results of State registration in all the States of this country having systems of registration, good, bad and indifferent, was presented for the past fifteen years by means of a table of registered death rates and a diagram The favorable and unfavorable facts bearing upon general registration were noted, and suggestions made whereby a fairly representative, though partial, return of mortality from a large part of the United States may be obtained until the general advance in populousness will admit of general registration Among these means are 1, the promotion of municipal registration, and a fuller utilization of the results of such registration, 2, supporting the work of the United States Weather Bureau of the Department of Agriculture, in its studies of sanitary climatology recently undertaken, 3, extension of the methods employed by Dr Billings in the compilation and study of the mortality statistics of the eleventh census together with the establishment of a permanent division of vital statistics as an important part of any proposed permanent census organization, 4, prevention of retrograde action on the part of any States sufficiently advanced in wealth and populousness to support accurate systems of registration It was further urged that the attention of the boards of commissioners appointed by many States for the purpose of securing greater uniformity of statute laws, be called to the importance of uniform legislation relating to the registration of births and deaths

There was no discussion on this paper

Dr Charles Denison introduced a series of resolutions favoring the creation of a National Department of Health, with special reference toward prohibiting the immigration to this country of diseased and otherwise unfit persons, also with power to guard against the introduction of contagious and infectious diseases, which were, under the rules, referred to the Executive Committee

Dr Henry D Holton moved, duly seconded, that when the Association adjourns on Friday, it does so to reconvene at Colorado Springs on Monday morning, the 7th inst, at 10 o'clock, for a short session The motion prevailed

The President announced the following gentlemen to constitute the Special Committee in reference to the "International Pollution of Waters Problem," as suggested during the forenoon of Tuesday's session Dr P H Bryce, Rudolph Hering, Dr C O Probst

The report of the Auditing Committee upon the Treasurer's annual report was next heard The report stated that all vouchers for disbursements of funds, and the entire report of the Treasurer was found correct The report was adopted

Dr Wilbur submitted the following resolutions, which were referred to the Executive Committee

Resolved, That the American Public Health Association cordially commends the action of the Weather Bureau of the United States Department of Agriculture in undertaking the collection of data relating to sanitary climatology

Resolved, That the American Public Health Association indorses the method first employed in the last United States census, of studying the vital statistics of certain American cities, as registered by local authority, for a series of years, and recommends that such method of treating vital statistics be carried out, so far as may be practicable, by the twelfth United States census for each year of the present decade Inasmuch as the collection of accurate vital data implies continuous, and not intermittent, action on the part of the central registration authority, it is obvious that a permanent division of vital statistics as a part of a permanent census bureau, is essential to the proper conduct of this important branch of the decennial census

Resolved, That a committee be appointed to prepare a draft of a registration law (or to formulate the principles to which a registration law should conform) suitable for adoption by States not having at present an accurate system of registration of births and deaths

Resolved, That a committee of the American Public Health Association be appointed to present to the boards of commissioners appointed by certain States to promote greater uniformity of statute laws, the importance of uniformity in the methods of registration of births and deaths in the several States of the Union

The Association then adjourned until 10 o'clock A M, Thursday

THIRD DAY—THURSDAY, OCTOBER 8

The Association did not convene until 11 o'clock owing to the protracted session of the Advisory Council, which held nearly a two hours' meeting during the forenoon President Bailey presided The first announcement was a report from the Executive Committee on the resolutions offered by Dr Wilbur during the preceding afternoon The Committee recommended that the resolutions be submitted to the Committee on Nomenclature of Diseases and Forms of Statistics, which upon motion duly seconded was so ordered After a number of announcements by the chairman of the Local Committee of Arrangements, the first paper announced on the program was on

NATIONAL LEGISLATION FOR THE CARE OF THE PUBLIC HEALTH, by Dr Wm P Munn, *Commissioner* of Health, Denver Colo, in which he said the failure of Congress to support the National Board of Health which ended its existence some ten or twelve years ago has been a source of deep regret to working sanitarians of the whole country It seems to be an axiom with our national legislators that cattle and hogs are of infinitely more importance than are human beings There are, therefore, in existence in this country half a dozen kinds of institutions whose existence depends upon the amount of noise they make about the investigation of diseases of the great American Hog and other animals whose welfare is of much importance from a monetary standpoint, to the agricultural classes The medical profession has for a number of years been asking Congress, with little apparent prospect of success, to establish a Department of Public Health, which shall give to the interests of human beings at least as much attention as has been bestowed in the past upon farm animals Congress has practically told the medical profession that the interests of human beings are not of sufficient importance to demand national legislation for their protection It is apparently futile to demand of Congress a recognition which it is so loath to give For this reason I have thought of making a proposal of a different nature, which it is hoped will not arouse antagonism, and being based upon the same general plan as that which has been so uniformly successful in securing recognition for the agricultural element of our nation, will at the same time appeal to the selfish interests of the various Congressmen in making an appropriation for expenditure by the various State authorities and to this extent strengthening certain already existing State institutions, without the State itself being forced into any further expenditure for the purpose Briefly, the proposition is this to establish in each State and Territory in connection with each State Board of Health now established, or which may hereafter be established a State Laboratory of Hygiene which shall be supported by an annual appropriation from the National Congress The plan is formulated upon the same basis as that upon which was established the agricultural experiment stations in connection with the various agricultural colleges in each State These experiment stations have been an unqualified success in many of the States, and have been instrumental in arousing an enthusiasm among scientific agriculturists and promoting sensible experimentation among farmers It is hoped that a similar beneficial influence would be exerted by the establishment in each State of a Laboratory of Hygiene in connection with the State Board of Health In States where no State Board exists, the fact that the Congressional appropriation might be available would be a sensible stimulus to the enactment of statutes creating a State Board State Boards having the usual dribbling allowance that is made for their support by the average Legislature, because the doctors composing their membership are not politicians of sufficient influence to secure proper recognition, would be placed upon a firm financial footing and made capable of doing their proper work and wielding their proper influence in their respective communities The many advantages that would accrue to sanitary science from the coöperation of forty or more laboratories, working by coördinate methods upon similar problems can not be more than hinted at The vast improvement which would follow in the sanitation of all local communities in the natural course of events should succeed to the positions of local health officers now only too often held by pot-house politicians, would result in an incalculable saving of human lives

I submit the proposed bill without further comment

An Act to establish Laboratories of Hygiene in connection with State Boards of Health existing by law in the several States

SECTION 1—Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That in order to aid in acquiring and diffusing among the people of the United States useful and practical information on subjects connected with public health and to promote scientific investigation and experiment respecting the principles and applications of hygienic science, there shall be established under the direction of the State Boards of Health in each State or Territory established, or which may hereafter be established, a department to be known and designated as a "Laboratory of Hygiene"

SEC 2—That it shall be the object and duty of said Laboratories of Hygiene to conduct original researches or verify experiments upon the diseases to which human beings are subject, and methods of prevention of the same, the chemic composition of human and animal substances of various kinds, the production within the animal organism of toxins and antitoxins, the comparative advantage to human beings of residence in certain localities and under certain climatic and meteorologic conditions, the effect upon the health of human beings of varying conditions of soil atmosphere, altitude, occupation, food, drink, clothing and dwelling places, the scientific and economic questions involved in the study of disease and disease prevention and such other researches and experiments bearing upon the health of human beings as may in each case be deemed advisable having due regard to the varying conditions and needs of the respective States and Territories

SEC 3—That in order to secure as far as practicable, uniformity of methods and results in the work of said laboratories, it shall be the duty of the Supervising Surgeon General of the Marine-Hospital Service to furnish forms, as far as practicable, for the tabulation of the results of investigation or experiments, to indicate from time to time such lines of inquiry as to him shall seem most important, and in general, to furnish such advice and assistance as will best promote the purpose of this act It shall be the duty of each of said laboratories annually, on or before the first day of February, to make to the Governor of the State or Territory in which it is located, a full and detailed report of its operations, including a report of its receipts and expenditures, a copy of which report shall be sent to each of said laboratories, to the said Supervising Surgeon-General of the Marine-Hospital Service and to the Secretary of the Treasury of the United States

SEC 4—That bulletins or reports of progress shall be published at said laboratories at least once every six months, one copy of which shall be sent to each newspaper in the States or Territories in which they are respectively located, and to all public health officers and to such other persons actually interested in matters of public health as may request the same so far as the means of the laboratories will permit Such bulletins or reports and the annual reports of said laboratories shall be transmitted in the mails of the United States free of charge for postage, under such regulations as the Postmaster General may from time to time prescribe

SEC 5—That for the purpose of paying the necessary expenses of conducting investigations and experiments, and printing and distributing the results, as hereinbefore prescribed, the sum of $15,000 per annum is hereby appropriated to each State, to be especially provided for by Congress in the appropriation from year to year out of money in the Treasury, to be paid in equal quarterly installments, on the first day of January, April, July and October of each year, to the treasurer or other officer duly appointed by each of said State Boards of Health, to receive the same, the first payment to be made on the first day of October, 1897, Provided, however, that out of the first annual appropriation so received by any laboratory, an amount not exceeding one-fifth may be expended in the erection, enlargement or repair of a building or buildings necessary for carrying on the work of said laboratory, and thereafter an amount not exceeding 5 per centum of such annual appropriation may be so expended

SEC 6—That whenever it shall appear to the Secretary of the Treasury, from the annual statement of receipts and expenditures of any of said laboratories, that a portion of the preceding annual appropriation remains unexpended, such amount shall be deducted from the next succeeding annual appropriation to such laboratory, in order that the amount of money appropriated to any laboratory shall not exceed the amount actually and necessarily required for its maintenance and support

SEC 7—That nothing in this Act shall be so construed as to impair or modify the legal relations existing between any of the said laboratories or Boards of Health and the government of the States or Territories in which they are respectively located

SEC 8—That in States having Boards of Health entitled under this section to the benefits of this Act, and having also Laboratories of Hygiene established by law, separate from said Boards of Health, such States shall be authorized to apply such benefits to investigations, researches at laboratories so established by such States, and no Legislature shall by contract, express or implied, disable itself from so doing

SEC 9—That the grants of moneys authorized by this Act are made subject to the legislative assent of the several States and Territories to the purposes of said grants, Provided, that payments of such installments of the appropriation herein made as shall become due to any State before the adjournment of the regular session of its Legislature meeting next after the passage of this Act shall be made upon the assent of the Governor thereof, duly certified to the Secretary of the Treasury

SEC 10—Nothing in this Act shall be held or construed as binding the United States to continue any payments from the Treasury to any or all of the States or institutions mentioned in this Act, but Congress may at any time amend, suspend or repeal any or all of the provisions of this Act

There was no discussion upon the foregoing topic or resolutions

An abstract of a report by E B Weston, C E, of Providence, R I, upon "Bacterial Results from Mechanical Filtration," was read by Dr Gardner T Swartz (This paper will be printed in the JOURNAL hereafter)

The next paper was presented by DR S H DURGIN,

ON MEDICAL INSPECTION OF SCHOOLS

The author said It is my purpose to give a brief statement of how work is done in Boston, and the result of four months work, as the machinery to do this was set in motion Nov 1', 1894 The statistics given showed that over one thousand cases of contagious and infectious diseases were detected in time to prevent a spread of the contagion by the medical inspector The city is divided into fifty school districts, giving an average of about four school houses and 1,400 pupils to each district One physician was appointed by the Board of Health for each district at a salary of $200 a year It is his duty to make a visit to each master of schools daily, soon after the beginning of the morning session The master receives from each of the teachers in the district, early reports as to the appearance of symptoms of illness in any pupil under their charge These reports are given to the visiting physician who at once examines the child and makes a record of his diagnosis and action, if the physician finds the child too ill to remain in school, it is sent home for the care of the parents and the family physician

Only favorable reports have been made concerning the operation of the plan The corps of medical men serve an excellent purpose in the control of contagious disease The work is generally approved by the medical profession, by school teachers, and the community at large *For* $10,000 a year, the teachers and 70,000 school children have the benefit of well selected medical oversight

The succeeding paper was a very voluminous one, namely, "Report of the Committee on the Disposal of the Dead," which was read by the Chairman, Dr Charles O Probst It was largely historical, as the committee had taken considerable pains to gather most valuable statistics regarding cremation in this country The report will be printed in full in this JOURNAL later

DR A WALTER SUITER, of Herkimer, N Y, followed with a paper, entitled,

ON THE DISPOSAL OF THE DEAD, HAVING SPECIAL REFERENCE TO THE PREVALENT PRACTICE OF EMBALMING

Herewith is a very brief synopsis as the paper in its original form will be published in the JOURNAL next month

"From remotest antiquity to the present time, topics relating to the disposal of dead bodies have been universally interesting No subject has been more carefully studied from all points of view, and yet it is not inconsistent with facts to state that no material advancement as to methods of preservation or final disposition has been made over those which were practiced more than twenty centuries ago Indeed, there is a growing belief in the public mind that to return to the custom generally in vogue previous to the Christian era (cremation) would solve many perplexing problems with which sanitarians are not unfamiliar"

The Doctor referred to the customs of mummifying the bodies of Egyptians and the practice of cremation in Greece and Rome The common custom of burial of the dead he thought obtained originally from the Chinese

"According to early chronologic records, no branch of art was cultivated in higher degree than that of the embalming of the human corpse Affection and superstition—always the greatest motive powers of the world—together with the prevalent fanciful ideas associated with death and subsequent everlasting life, all combined to give the greatest prominence to the extraordinary, elaborate and costly methods which were employed in the remote periods of civilization for the preservation of dead bodies in order that they might be kept uninterred"

In regard to the present custom of embalming, the essayist argued that there is too much carelessness shown in doing the work by undertakers, without legal regulation to obviate it It is the doorway to an enormous and systematic deception—a commercial fraud, *in fact*, as a comfortable fee is charged for the service

"To illustrate," said the Doctor, "take the case of General Grant Extraordinary precautions were taken to preserve the body The embalming was done in accordance with methods in vogue, but a few days later when the remains reached Albany, the well known features of the distinguished man were almost unrecognizable"

The danger of embalming as a means of concealing crime by poisoning was referred to, and incidents cited to show that it had been done

The result of careless embalming, the essayist claimed was not dangerous 'Gallons of poisonous solutions are squirted into bodies indiscriminately, which are in an incredibly short time imbibed by other bodies in cemeteries and are absorbed by contiguous soils and streams and also wells that are fed by subterranean waters which receive the percolations of graveyards filled with bodies thus treated For example, a recent examination of the waters of Scajaquadu Creek, which flows through Forest Lawn Cemetery, Buffalo, were found to be impregnated with considerable quantities of arsenic of this kind used in the prevalent method of embalming"

A law to regulate embalming, the essayist considered imperative

At 1 30 o'clock the Association adjourned until evening

Third Day—Evening Session

The Association reconvened at 8 o'clock in Unity Church, with President Bailey presiding

The first paper was read by Dr S E Solly, of Colorado Springs, Colo ,

ON THE INFLUENCES PECULIAR TO HIGH ALTITUDES UPON SANITARY CONDITIONS

The paper was a carefully prepared treatise The author said in part With diminished barometric pressure we have less pressure upon the body, hence a diminished amount of oxygen High altitude increases the red corpuscles in the blood The heart is increased in strength and made larger, and the blood has greater ability to absorb oxygen The lungs are rendered more powerful to resist germicidal tendencies There is a more vigorous circulation, hence more violent inflammatory action may supervene, as in acute pneumonia Better results are attained in anemia, or neurasthenia, or where anemia is a prime factor in a disease, also in chronic germ disease as in tuberculosis The germicidal power of the blood is strengthened Typhoid and scarlet fevers and measles are of much milder form than in a lower climate and oftentimes they are unrecognizable Convalescence is more rapid and complete than at sea level In elevated climates there is greater increased precipitation If dizziness supervene, this lessens the temperature upon the body Sunstrokes as a matter of course are rare Myalgias and pleurisy are frequent Dry air, sunlight and sun heat increases nerve tension Dry air allows the sun to shine with greater brightness, therefore with more vivifying effects On the other hand, if the physique is depressed, the effects will be as fatal as in lower climates Horses raised in high regions had been able to endure much fatigue It was the same with men who had a larger lung expansion The dryness improved the action of the skin, liver and bowels in one class of persons, while in another it decreased their action Disease is less easily acquired in high altitudes Nevertheless, people living there must observe as proper sanitary precautions as though they lived elsewhere The author also argued that the amount of hemoglobin in the blood is increased The chest expansion as is remarked frequently by almost all observers is augmented, and especially are the apices of the lungs of the native born children and old residents better filled with air Further deductions were to the effect that where there are other deficiencies in the blood, provided that other conditions do not exist high altitude is a most important factor and influence in the treatment as well as prevention of disease

Dr Henry Sewall, in the discussion said that no such paper should be read without some discussion upon it, as our ignorance of the physiologic condition and vital forces that high altitudes exert upon the human economy is so great No such field for the study of any similar topic presents itself to my mind as this one of the simple problems of blood pressure, etc We should all take up the study of this subject, of the effect of high altitudes upon hearts, to study if their area of dullness is increased, also regarding the increased or decreased action of the liver and skin If there is a decreased action of the skin, the kidneys must reply He has treated cases, and illustrated his remarks, where the urinary secretion is enormous and where hyalin, granular and epithelial casts are very common indeed, due, as he stated, where there was no pathologic condition, but attributable to a less active condition of the skin He thought it was a shame that those who lived in high altitudes did not experiment more upon the effect of high altitude on health He pleaded for individual observation for researches in this altitude and an earnest desire for truth Regarding his personal experience , years ago, before removing to Colorado, a "homeopathic" physician advised him not to do so, as he would die within a week He came here, however, and was glad to be disappointed

Dr Domingo Orvananos, of the city of Mexico, who followed, stated that there was an institution in his city where experiments were made upon the effects of altitude upon disease The average number of red corpuscles in the blood in the high altitude of the city of Mexico, were several millions more than in persons who dwell in a low altitude Consumption in the first and second stages was very easily cured Pleurisy is not as common in Mexico as it is here The remainder of his remarks were confined principally to the methods of heating the houses in Mexico

Dr Peter H Bryce spoke at some length regarding the prevalence of catarrhal troubles and diphtheria which prevails unusually in the central States of the country, and of the large mortality from the latter disease in his province, as well as in certain portions of the United States In Ireland the mortality of those dying of diphtheria is one third less than in England In England, those who succumb to diphtheria are one half less than in Ontario, hence her record is better than in Canada, while in Ontario the mortality from diphtheria is the same as in the United States If the methods of heating dwelling houses have anything to do with the prevalence of diphtheria, or of inducing diphtheritic throats and so-called catarrh, wherein is the relation between abnormal dryness and these maladies? He desired to know about the frequency of catarrh said to exist in this climate?

Dr Carl Wende desired a little more information regarding the presence of hyalin casts in the cases cited by Dr Sewall

Dr Eduardo Liceaga, of Mexico, stated that the climate of Mexico is divided into three zones High altitude, which is 2,000 meters above sea level, medium altitude which is below this and low altitude or sea level In the latter zone, tubercular disease is very frequent, and microörganisms were readily recognized there The disease is difficult to cure In the medium altitude, phthisis prevails to a very much less extent, while at 2,000 meters, or above this, it does not exist at all

Dr Gregorio Mendizabal, of Orizaba, Vera Cruz, Mexico, briefly stated his observations by calling attention to the influence of humidity in different litttle towns of the Republic, on the development of phthisis Dampness also has a great deal to do with development of microorganisms and this disease

Dr Solly concluded by saying We cry loudly for careful research and the study of facts regarding the influence of high altitudes upon the human system Physiologists state it as a broad proposition that a high climate is good for thin blooded people He answered Dr Bryce by stating that diphtheria was not uncommon on high ground, and when it did exist it was not so contagious as on low ground, but if it became contagious it was likely to be very virulent The peculiar conditions of the dryness of the upper air'passages render them more easy for lodgment of germs, and then disease is more serious in high altitudes, and yet high altitudes are prejudicial to germ diseases As regards humidity, we know this will induce tubercular difficulties Cold and dampness combined is also a peculiar element to bring it on The relative frequency with which phthisis is induced might be studied and compared, in a cold damp climate and a hot damp climate Catarrhal troubles exist frequently and indiscriminately in different climates

The next topic announced on the evening's program was the "Report of the Committee on the Abuse of Alcoholic Drinks from a Sanitary Standpoint," and was made by Dr Felix Formento, Chairman, of New Orleans, La The subjoined excerpt is herewith presented, as the report *in toto* is a most extensive one

The crusade against alcoholism is universal, and the question is now being investigated in a most scientific and thorough manner Physicians, clergymen, statesmen and others have banded themselves together, hoping to eradicate the abuse of alcoholic drinks

Alcoholism does not apply to taking a glass of pure wine at meals or a glass of pure whisky The use of beers and wines at meals might be commended—both were valuable because of their nutritive qualities , they helped digestion and invigorated without intoxicating He defined alcoholism to mean the chronic excessive use of alcoholic drinks The drunkard should not be confounded with the gentleman who takes his wine at table The habitual use of strong liquors can not be too strongly condemned

French brandy, when pure was less injurious than either rum or whisky In wine growing countries like Italy, alcoholism was almost unknown One of the committee, it was related lived six years in Italy, and never in that time saw a really drunken man, but only jolly, good-natured ones This incident was mentioned in connection with a statement that there is less intoxication in wine growing countries and districts than in portions of the country where no wines are grown The worst alcohol is the potato article, which contains the deadly fusel oil In America many of the distinguished men of the country are addicted to the use of alcohol, and it seemed to be the national vice This is the only country in the world where the people high and low drink standing, without eating, and without being thirsty

Alcoholism is one of the potent factors in crime, suicide and poverty It peoples the hospitals it is responsible for cripples, epileptics, and while it exists mostly among the and invade the adjacent muscle bundles The arteries were, in the main, free from any changes

The muscle fibers themselves showed extensive retrogressive changes, being at times the seat of a simple atrophy, at other times vacuolated or fatty In some of the connective tissue masses the muscular tissue had disappeared completely, leaving sometimes heaps of pigment behind In some places one could find zones of hyalin necrosis in the myocardium adjacent to markedly dilated veins These changes were not evenly distributed, being most marked in the walls of the ventricles, less in the interventricular septum and still less marked in the auricles The intensity of these changes was greatest in those individuals who had suffered from repeated attacks of asystole and in whom the final condition of cardiac weakness had lasted the longest

It is quite clear that such changes belong to the cirrhoses and that the point of origin was in the venous walls The morbid changes described can consequently be included under the name of venous cirrhoses in contradistinction to the arterial cirrhoses which develop in connection with lesions at the aortic valves

How can the genesis of this venous cirrhosis be explained? The right ventricle has not sufficient reserve power and in consequence early attacks of asystole develop in mitral disease During such an attack the circulation of the blood in the veins is hindered The venæ cavæ can not empty themselves readily, stasis in the liver and kidneys, and edema come on In addition to the caval veins, the coronary and small accessory coronary veins also empty into the right auricle and the coronary veins therefore meet with the same difficulties as the caval under these conditions and, consequently, a stasis develops in the myocardium as well as in the liver, kidneys and elsewhere The anatomic changes found in the myocardium show this inference to be correct Repeated stasis results in retrogressive changes in the muscle fibers and these lesions enfeeble contractility and renewed disturbances of compensation occur after slighter provocation Finally, hyperplasia of the connective tissue ensues and the heart muscle at last is no longer able to perform its functions There arises a *circulus vitiosus*, inasmuch as the lessened contractility increases the stasis in the changed heart muscle which on its side diminishes the power of contraction

BANTI considers, as will have been observed, the mitral lesions as due to endocarditis, and the aortic lesions as due to atheroma This is undoubtedly true in the majority of cases, but it can not be denied that there are aortic lesions of inflammatory nature, and mitral of atheromatous, and the myocardial changes that cause disturbances of compensation in such cases he does not attempt to discuss

The essential outcome of BANTI's investigation may be stated in this way,—that in aortic valvular lesions, due to an atheromatous process, the principal cause of the final disturbance of compensation is an arterial sclerosis of the myocardium, while in mitral lesions, due to endocarditis, compensation is disturbed and at last destroyed on account of a myocardial sclerosis of venous origin

POPULATION AND LONGEVITY

Some years ago, a prominent medical writer published an account of an ideal "City of Health," an assumedly impossible municipality in which all preventable causes of disease were avoided, and the death rate lowered to two or three in the thousand by faultless construction and organization and absolutely perfect sanitation The article was widely quoted in the lay and medical press, and everywhere with approval, until a mathematician or an actuary ventured to figure on the possibilities and demonstrated that with such a death rate without a corresponding reduction in births, there would not, in a relatively very few years, be standing room for the population in such a community

Man is a very prolific animal and the procreative instinct is one of the strongest in our nature, certainly this is so with what has been called in continental Europe, the proletariat, a class that includes mainly the improvident poor, and therefore a large proportion of the population of the great cities in this country, as well as abroad Prudential considerations have little weight with this class of individuals, and were the death rate low and longevity the rule, the inconveniences of over-population would soon be manifest As it is, the urban tendencies of this class and the consequent degeneracy (which properly signifies any tendency to race decay), may possibly save us from having to meet with the Malthusian problem in a severely practical form

If the average of human life were 100 years, as it has been claimed it should be, and were perfect sanitation and the reign of universal peace, the ideal of philanthropists, to be realized, the near future would show an inconveniently over-populated world, unless some providential dispensation stepped in to give us elbow room or some social regulation were adopted, such as raising the marriageable age, ruling out all but the physically, morally and mentally best fitted from the privilege of procreation, or some other similar device It is doubtful whether mankind would be any happier under such conditions, but they would be found indispensable in the social Utopias such as that of BELLAMY, were these ever realized The rock of population is the one on which, as MR BENJAMIN KIDD in "Social Evolution" says, all these social systems split, it is the problem of which their authors take no account Over-population would work its own cure through intensified human misery and degeneracy, possibly, as has repeatedly happened with the lower animals in localities, with the more or less complete extinction of the species

While, however, one can thus even say a good word for human degeneracy, as perhaps on the whole a safety valve for populations collectively, it is individually an evil, and one that needs to be vigorously met Man can not control evolution, and so far as he can be effective, he must use his efforts to combat obvious evils, and leave general results to work out themselves There is therefore no excuse for lowering our sanitary ideals The problems here suggested are not for immediate solution, and matters can be very much improved before unusual longevity and general perfection in health conditions render them at all practical But they are perhaps worth considering, if it is only to temper a little our hygienic air castles and as a sort of consolation for our unavoidable sanitary failures

'DRUGS MANY REMEDIES FEW"

The current issue of *New Remedies* quotes this caption from the *Hospital* as being a succinct summary of the present pharmaceutic situation Since 1880, "while two hundred remedies have been introduced, probably not more than twenty are in daily use" Twenty years ago the words "new remedies," designated botanic products introduced as newly discovered agents of extraordinary therapeutic value Ten years later, synthetic chemistry, beginning with antipyrin (the first notable success) usurped the title And now bacteriology is fast pushing the autocrat of the last decade into retirement

If present activity in, and enthusiasm over, serums, antitoxins and extracts continue, and are justified by results, we may have to discard all our old materia medica before the end of this century But on this point the *New Remedies* is not sanguine, its sympathies being somewhat closely identified with the products of the manufacturing chemist, although free to admit that these interests have been hurtfully overdone

The therapeutic pendulum has swung, first away from botany, next away from chemistry and presently, it is predicted, the swing will be away from bacteriology We note, in the foreign letter of the *American Practitioner* the following intimation, that our German confrères are disposed to swing back to botany

"An important step is about to be taken by the Berlin Pharmaceutical Society, for the purpose of extending the world's knowledge of poisonous and healing plants A central office is to be established for collecting and publishing reports from every quarter of the globe on the botanic, chemic, and pharmacologic discoveries in plants of a healing or poisonous nature The Berlin Society does not intend merely to collect unknown facts, but hopes to encourage further inquiries in a field which has not yet been fully explored"

For the present, however, the German bacteriologists are said to be so fully occupied with their respective original researches, that they have no time or patience to expend upon students from abroad Some ambitious students from this country have returned, not without disappointment at the scant attention they were able to obtain at some of the foreign laboratories, chiefly for the reason that the teachers are, for the time being, preoccupied with their own special investigations

GENUINE DIPHTHERIA OF THE SKIN

A few cases of genuine diphtheria of the skin have been described, in which the diagnosis rests upon the cultural and microscopic demonstration of Loffler's bacilli Brunner[1] describes four cases of this unusual infection of the skin upon the fingers, Neisser[2] found diphtheria bacilli in a membranous deposit near the anus, Treitel[3] in an excoriated area near the external ear, Vucetic[4] describes an extensive diphtheria of the skin of the neck in which the bacilli were demonstrated microscopically but not in cultures Feer,[5] Escherich[6] and Townsend[7] describe genuine diphtheria of tracheotomy wounds Park[8] has recorded two cases of genuine diphtheria in finger wounds in physicians, the infection following tracheotomies, and Wright[9] details seven instances of diphtheric infection in excoriations and exulcerations of the skin as, for instance, in connection with paronychia and mastoid abscess Abel[10] has also described diphtheria in a wound of the finger

In addition to these cases of wound diphtheria of the fingers, recorded by Brunner, Park and Abel, a new case is added by Zaufal (*Prager medicinische Wochenschrift*, 1895) This case occurred in a child, 4½ years old, with fatal laryngeal and pharyngeal diphtheria He succeeded in demonstrating in the microscopic sections, as well as in cultures, that Loffler's bacillus was present in an infiltration, 1 cm square in size, situated upon the ulnar margin of the first phalanx of the right index finger The center of this area was ulcerated and covered with a fibrinous deposit The cultures of diphtheria bacilli obtained possessed a considerable degree of virulence as 1 ccm of a two days' old bouillon culture killed a guinea pig, 300 grams in weight, forty hours after intraperitoneal injection In addition to the diphtheria bacilli, the yellow pus coccus was isolated from the infiltration in the skin of the finger, and Zaufal regards the case as an instance of genuine wound diphtheria which was engrafted upon a scratch in the skin that had been infected with the staphylococcus pyogenes aureus

MAJOR A C GIRARD

Major A C Girard, U S Army, who has been stationed at Fort Sheridan, Chicago, for the past four years, has been ordered to Fort Douglass, Salt Lake City, Utah Major Girard was given a farewell reception and a dinner by Dr F B Turck and some of his medical friends in the city, who view his departure with regret

The occasional contributions of Major Girard which have appeared in these columns, not less than the one in this issue of the Journal show him to be an accomplished surgeon, and one no less gifted with the pencil than the pen Few of our profession are able to so skillfully illustrate their own articles

The medical profession of Salt Lake will receive a notable addition to their ranks in the person of Major Girard

CORRESPONDENCE.

Association of American Medical Colleges.

Chicago Oct 9, 1895

To the Editor —The decision of the Judicial Council is asked upon the following propositions

1 Is there any rule to prevent colleges, members of the Association, from admitting students in September, 1895, and allowing them to graduate, after taking three full courses of lectures, ending in 1898?

2 If such rule exists and is enforced, what will be done to those colleges, members of the Association, who violate the rules? Shall recognition be refused to diplomas issued to students in 1898 because they began the study of medicine in 1895?

3 Students A and B matriculate in 1895 A graduates in 1898, B in 1899 Are the two on equal footing according to the rules of the Association?

DECISION

1 It is the judgment of the Council that there is no rule of the College Association preventing any of the members matriculating students in September, 1895, and allowing them to graduate after taking three full courses of lectures of six months each, in three separate years, ending in 1898

2 The Council is now prepared to decide what should be done with colleges which violate any of the rules of the Association

3 It is the judgment of the Council that A and B must be recognized as of equal respectability Because the progressive advancement in methods of teaching, *pari passu* with the increasing demands for more lengthened collegiate instruction, must have a definitely stated date of beginning, and can not be made retroactive If this rule could be made *ex post facto*, all the elder members of the profession might be rated as of inferior standing to those gentlemen who now graduate under our graded system of instruction, and are required to have attended more terms, and for a longer period of time than was formerly exacted

Did Not Boom an Irregular Device

Chambersburg, Pa, Oct 7, 1895

To the Editor —I send you by this mail, a reprint of my article on "Electricity," not so much on account of any merit it may possess, but to demonstrate to you how little your reporter understood what I was talking about when he wrote you the report of the proceedings of our State Society He must have been a very serious man to fail to see that I was poking fun at "Electropoise," and write you that I said that *argon* was what was driven into the system, etc

Look at the report, and then at the latter part of my article, and determine whether I was too ponderous at my fun, or be too dull of comprehension

No serious harm has been done—the "Electropoise" men have not yet thanked me for my ad through your Journal, nor yet have they "gone for me" for my temerity in handling their pet instrument Very truly yours,

Geo S Hull, M D

ASSOCIATION NEWS

Section on Ophthalmology —Report of the Secretary

Place of meeting, gentlemen's reception room, Music Hall Meeting called to order at 3 30 p m, by the chairman, Edward Jackson, of Philadelphia, Pa, who delivered the Annual Address, "The Strength of the Different Mydriatics and Myoptics" At the close of the address a resolution was passed limiting time for reading of papers to ten minutes and discussion to five minutes for each speaker A R Baker, of Cleveland, Ohio, read a paper on "Incipient Cataract," followed by J E Weeks, of New York, with "The Operative Treatment of Immature and Some Forms of Zonular Cataract"

The discussion on these papers was opened by Geo E Frothingham, of Detroit, Mich, followed by Herman Knapp, of New York, Joseph A White, of Richmond, J L Thompson, of Indianapolis, Jas A Lydston, of Chicago, F C Hotz, of Chicago, S D Risley, of Philadelphia, A J Erwin, of Mansfield, Dudley S Reynolds, of Louisville Discussion was closed by J E Weeks, of New York

The first of the papers on "Operations About the Eye" was read by M W Zimmermann, of Philadelphia, Pa, on "Practical Points on Anesthesia for Operations about the Eye," Dr Tyree, of Kansas City, and Eugene Smith, of Detroit, being absent, the next paper of the series was read by W B Johnson, of Paterson, N J, on "Transplantation of Skin in Plastic Operations on the Eyelids" He was followed by F C Hotz, of Chicago on "Skin Grafting in Ectropion and Entropion" The next paper was by Herman Knapp, of New York, on "Transplantation of a Strip of Skin into the Intermarginal Space of the Lids" The last of the series was by Herbert Harlan, of Baltimore, Md, on "Some Cases of Restoration of Eyelids with Exhibition of Patients" The discussion was opened by R A Reeve, of Toronto, followed by H V Würdemann, of Milwaukee, D S Reynolds, of Louisville, E J Bernstein, of Baltimore, Lucien Howe, of Buffalo, J P Worrell, of Terre Haute, P D Keyser, of Philadelphia, S D Risley, of Philadelphia, G C Savage, of Nashville, Frank Allport, of Minneapolis, Hiram Woods, of Baltimore, Herman Knapp, of New York, and M W Zimmerman, of Philadelphia In the course of the discussion, patients were exhibited by Herbert Harlan and E J Bernstein

Wednesday, May 8—Morning Session

Meeting called to order at 9 10 a m By request the Chairman called for the report of the Committee on Legislation for the Prevention of Blindness which was presented by the Chairman, Lucien Howe, of Buffalo, N Y On motion by Leartus Connor, seconded by H M Starkey, the thanks of the Section were tendered and the committee extended L Webster Fox read a paper on "Evisceration of the Eyeball," upon which the discussion was opened by S D Risley, of Philadelphia, followed by G Oram Ring, of Philadelphia, F C Hotz, of Chicago E Oliver Belt, of Washington, H Gifford, of Omaha, L J Lautenbach, of Philadelphia, R C Hodges, of Houston, and discussion closed by L Webster Fox, of Philadelphia

The next paper was by Geo E de Schweinitz, of Philadelphia, Pa, on "Histologic and Bacteriologic Notes on Some Cases of Penetrating Wounds of the Eyeball with Experimental Observations on Certain Bacilli found in a Case of Post-Suppurative Panophthalmitis," discussion of which was opened by R L Randolph, of Baltimore followed by Harold Gifford, of Omaha

The next paper was by Harry Friedenwald, of Baltimore, on 'Hemorrhage into the Retina and Vitreous in young Persons, Associated with Evident Disease of the Retinal Blood Vessels—Remarks on the Formation of Vessels in the Vitreous in a Case of Immigrating Subhyaloid Hemorrhage", followed by E Oliver Belt, of Washington, D C on the 'Prognostic Significance of Albuminuric Retinitis," and by J T Carpenter Jr, of Philadelphia, Pa, on "Extensive Colloid Changes in the Choroid with Report of Cases" Discussion opened by Geo E de Schweinitz, of Philadelphia, B Alexander Randall, of Philadelphia, Harold Gifford of Omaha, Herman Knapp, of New York, and J T Carpenter Jr, of Philadelpha

Wednesday, May 8—Afternoon Session

Called to order at 3 P M The Nominating Committee reported as follows for President, Lucien Howe of Buffalo, for Secretary, Frank Allport, of Minneapolis Upon motion of J H Thompson, seconded by G C Savage, it was resolved that the report of committee be accepted and the Secretary was instructed to cast the ballot electing the above named officers A series of papers then followed upon the "Ocular Muscles," the first of which was by Leartus Connor, of Detroit, Mich, "The Technique of Tenotomy of the Ocular Muscles" Samuel Theobald, of Baltimore, Md, 'The Slight Effects Sometimes Produced as the Results of Free Tenotomies of the Ocular Muscles for Heterophoria", H F Hansell, of Philadelphia, Pa, "The Limitations of Tenotomies of the Ocular Muscles", C H Thomas, of Philadelphia, Pa, 'Tendon Advancement with a Special Indication for its Employment", G C Savage, of Nashville, Tenn, 'The Indications for Advantages and Technique of Muscle Shortening" *Geo T Stevens of New York*, opened the discussion by reading a carefully prepared paper followed by S D Risley, of Philadelphia, A J Erwin of Mansfield, Samuel Theobald, of Baltimore, Herman Knapp, of New York, F C Hotz, of Chicago, G Hermon Thomas, of Philadelphia, G Edgar Dean, of Scranton, Frank Allport, of Minneapolis, Leartus Connor of Detroit, G C Savage, of Nashville, G T Stevens, of New York C M Hobby being absent the next papers were by Hiram Woods, of Baltimore, 'To What Extent Should Recently Suggested Methods of Muscular Exercise Displace Tenotomy in the Treatment of Heterophoria" J W Park, of Harrisburg, Pa on '*Practical Points Gained in the* Treatment of 1,000 Cases of Insufficiency of the Ocular Muscles", E J Bernstein, of Baltimore, Md, 'Some Remarks on Paralysis of the Superior Rectus Muscle", followed by G M Gould, of Philadelphia Pa, on "Some Findings Concerning Muscle Imbalance and its Treatment" The discussion was opened by Leartus Connor, of Detroit, followed by G C Savage, of Nashville, G H Price, of Nashville, Geo S Hull, of Chambersburg, R A Reeve, of Toronto, G Edgar Dean, of Scranton, Hiram Woods of Baltimore J W Park, of Harrisburg, and E J Bernstein, of Baltimore Henry Gradle, of Chicago, was absent but his paper on "Hysterical Insufficiency of Convergence," being in the hands of the Secretary was read by title

Thursday, May 9—Morning Session

Meeting called to order at 9 15 A M The first paper read was by J A Lydston, of Chicago Ill., "The Relationship Between the Eye and Brain" Next paper was by S C Ayres, of Cincinnati, Ohio, on "Lymphangeoma Cavernosum of the Orbit" Dr Ayres being absent, and his paper in the hands of the Secretary, it was read by title P D Keyser and C A Oliver being absent a paper by Flavel B Tiffany, of Kansas City, Mo on 'Ectopia Lentis," was read This was discussed by J L Thompson of Indianapolis, A R Baker, of Cleveland Harold Gifford, of Omaha, F C Hotz of Chicago, B A Randall, of Philadelphia, Herbert Harlan, *of Baltimore, S L Ziegler, of Philadelphia, J A Lydston*, of Chicago, R C Hodges, of Houston, and closed by Flavel B Tiffany, of Kansas City

P D Keyser, of Philadelphia, Pa, then read a paper on "A Case of Enchondroma of the Cartilage of the Upper Lid," which was discussed by F C Hotz, of Chicago, J L Thompson, of Indianapolis, S L Ziegler, of Philadelphia, and closed by P D Keyser

The paper of W H Wilder, of Chicago, on "Formalin as a Preservative Agent for Eye Specimens," was, in the absence of the author, read by title Dr F C Hotz exhibited the specimens, and made explanatory remarks He was followed by H V Würdemann, of Milwaukee, H M Starkey, of Chicago, E J Bernstein, of Baltimore, and Geo E de Schweinitz, of Philadelphia

The next paper was by H V Würdemann, of Milwaukee, on "The Infiltration Method of Anesthesia in Ophthalmic Practice," with demonstration This was discussed by Gilbert E Seaman, of Milwaukee, Geo E de Schweinitz, of Philadelphia, G Edgar Dean, of Scranton, J C Dunlevy, of Sioux City, Flavel B Tiffany, of Kansas City, A C Corr, of Carlinville, Ill, and closed by H V Würdemann The technique of the injection was shown upon the arm of one of the ophthalmologists present, and a patient was introduced by Harry Friedenwald, of Baltimore, with sebaceous cysts on the forehead who was operated on under anesthesia by this method for purpose of demonstration

Thursday, May 9—Afternoon Session

Meeting called to order at 8 15 P M B Alex Randall, of Philadelphia, presented the Report of the Committee on the Examination and Care of the Eyes during School Life After reading the report, Dr Randall read a paper on 'The Importance of Noting Slight Choroiditic Changes, especially Conus" These were discussed by P A Callan, of New York, S D Risley, of Philadelphia, A J Erwin, of Mansfield, Frank Allport, of Minneapolis, Frank Fisher, of Philadelphia, R A Reeve, of Toronto, Dunbar Roy, of Atlanta, G H Price, of Nashville, Lucien Howe, of Buffalo, L B Ryan, of Galesburg, Leartus Connor, of Detroit, G Edgar Dean, of Scranton, J L Thompson, of Indianapolis, and closed by B Alex Randall

Dr Mittendorf being absent, the next paper was read by H Bert Ellis, of Los Angeles, Cal, "A Study of the Refraction of 1,000 Eyes" Dr Southard, of San Francisco, being absent, *this was followed by S D Risley, of Philadelphia, on* "The Percentage of Symmetrical and Asymmetrical Meridians of the Cornea in Astigmatic Eyes" Dr H M Starkey followed with "Latent Astigmatism", L J Lautenbach, of Philadelphia, on "The General and Local Conditions that change Corneal Curvature" Discussion by Frank Fisher, of Philadelphia, Edward Jackson, of Philadelphia, A C Corr, of Carlinville, Ill, P A Callan, of New York, H M Starkey, of Chicago and L J Lautenbach, of Philadelphia

The Executive Committee reported the subject for collective study by special committee for the next year, 'Detachment of the Retina its Etiology and Treatment' They further suggested to the Section as a topic for study and presentation, 'Cases of Optic Nerve Atrophy of Obscure Origin" The chairman appointed on the first *committee* R L Randolph Chairman, 211 W Madison Avenue, Baltimore, Md F C Hotz, 36 Washington Street, Chicago, E E Holt, 723 Congress Street, Portland Maine, J E Weeks, 46 East 81st Street, New York, T E Murrell, 6th and Olive Streets, St Louis, Mo

On the second committee H V Würdemann, chairman, 805 Grand Ave, Milwaukee, G E de Schweinitz 1401 Locust Street, Philadelphia, H Friedenwald, 922 Madison Avenue, Baltimore, Md, C W Kollock Charleston, S C G Dunbar Roy, *56½ Whitehall* Street, Atlanta, Ga

Friday, May 10—Morning Session

Meeting called to order at 9 30 P M The only remaining paper of the program not having been read, whose author was present, was by A C Corr, of Carlinville, Ill, on 'Anomalies in Ophthalmic Practice" Discussion by J L Thompson, of Indianapolis, H V Würdemann, of Milwaukee, R L *Randall*, of *Baltimore*, and closed by A C Corr, of Carlinville

This completed the list of *papers The chairman* congratulated the Section on the scientific work of the meeting, and especially as it was the largest gathering of ophthalmologists ever held in this country (one hundred and six having registered) The Section then adjourned to meet the following year

H V Würdemann, Secretary

SOCIETY NEWS

The American Association of Gynecologists and Obstetricians —Dr Franklin H Martin delivered the following toast at the annual banquet of this Association

Mr President —The name, birth, policy and success of your society possess inspiration for as many toasts Its name reminds us of American gynecology Its time of birth coincides very closely with the new birth of medicine Its policy—genuine scientific work for our specialty—broad as our country in its membership, democratic as our republic in its constitution, commands respect Its success so remarkable that those once its opponents halt and applaud, is only accounted for by its magnificent and representative membership As President of the Chicago Gynecological Society, in a position to speak officially for the gynecologists of Chicago, I voice their sentiments when I say we are proud to have you honor our city with your presence You honored your society by calling it American In no place in America does the eagle scream louder or in more unmistakable tones than right here in Chicago

Your society came into existence with the new birth in surgery, when surgery as a science began to predominate, and surgery as an art began to recede In other words, with the renaissance of medicine Moss-covered and absolute traditions you left behind You got away from narrow provincialism and crossed the Alleghanies, the Rockies, and even annihilated the imaginary Canadian line which hitherto divided the Americans of the North from those of the South In this, as Chicagoans, we appreciate you and embrace you

Old foggyism was in its death throes before Chicago become a city In medicine and surgery *we* are *all* renaissance We have a code in Chicago broad enough even for your honorable secretary, which is indelibly impressed upon every one of our memories It is "Do unto others as you would that they should do to you, and the Lord help him who doesn't"

We know of but one country and, like you, we annex all competitors, and naturalize all foreigners Like you, without prejudice we take that which is good from all lands, and without regard to traditions we reject that which is useless, and that which we finally possess is indelibly stamped with the American eagle and henceforth becomes our own

It is such societies as yours, Mr President, which will make us more and more proud of that name—American—which will reiterate the fact every year with abundant proof of its truth, that American gynecology and abdominal surgery has from the beginning of modern medicine led the world

We must not forget, nor allow the fact to become obscured that anesthetics, without which gynecology would be impossible, were discovered and employed first by Morton of Boston

We must not forget, nor allow foreign authors to forget, that the first ovariotomy was performed by Ephraim McDowell

We must not forget nor fail to honor the fact that Gilman Kimball of Boston, proposed and executed the first abdominal hysterectomy for fibroids

We must not forget that modern plastic gynecologic surgery was founded by Marion Sims

We must not forget nor allow the fact to become obscured in literature, that the first modern vaginal hysterectomy was performed by Lane of San Francisco

We can not forget, nor should we, that the removal of the uterine appendages for the establishment of an artificial menopause was deliberately planned and executed by Robert Battey, coincidently with, but independently of two other great surgeons

And finally, gentlemen, we have not forgotten nor will it be forgotten as long as abdominal surgery has a history, that the principles of modern intestinal surgery were founded by Nicholas Senn

Gentlemen, for a young nation have we not the right to be proud of our achievements? Is there another nation, old or young, which can show so long a list of practical works which have been adopted as the most important legitimate life-saving procedures by the whole world? Take from gynecology and abdominal surgery those procedures initiated by Americans and our specialty would have no existence

So, Mr Chairman, we extend to you a Chicago welcome The important work your society is doing can not help but maintain our specialty in the front rank of the medicine of the world

And finally, let us as American gynecologists, in whatever society we work; cultivate a scientific conscience, so that we may interpret aright Cultivate a laudable ambition so that we may work with enthusiasm—and most of all cultivate *patriotism* so that American achievements will have their full importance in our hearts

Chicago Ophthalmological and Otological Society —Regular meeting held May 14, 1895, at 155 Dearborn Street[1] There were ten members and visitors in attendance Dr Hotz in chair

The minutes of the last meeting were read and approved

Drs W R Fringer and A B Hale were elected members

Dr Wilder said that the case of paresis of extrinsic muscles, reported by Dr Gradle, was now improving under potass iodid

Dr Coleman reported a case of gumma of the sclera Woman, 26, whose symptoms began early in winter V O S =20-200, marked conjunctival injection, iris discolored, no pupillary reaction, a gumma-like infiltration at upper and outer sclero-corneal margin extending into cornea With atropin and potass iodid no improvement took place and subconjunctival injections of corrosive sublimate were were used Under this treatment a cure rapidly took place

Also a case of hemiopia Woman, 37, confined last November, was unconscious for six weeks, fundus shows no retinitis, left homonymous hemiopia extending through macula, color fields for red and green much diminished, V each eye 20-20, pupillary reaction slightly subnormal Dr Tilley thinks that such cases are due to a toxic agent, chiefly syphilis He had a case very similar

Dr Tilley had a case of diplopia above and below horizontal line which disappeared in ten days Patient had a tooth pulled a few days before and piece of jaw was broken off Dr Wood reported case and showed sections of intra-ocular tumor Patient was over 40 No irritation, only slight increase of tension Nature of tumor rather obscure but probably glio-sarcoma

Dr Wilder thought it was a sarcoma

Dr Wood showed a combined red and blue gelatin mask for use before an electric furnace.

Dr Hotz gave a short account of the proceedings of the Ophthalmological Section at Baltimore

On motion the Society adjourned

103 State Street C P Pinokard, Secretary

NECROLOGY

John S Young, M D, of Brooklyn, died September 23, aged 63 years The cause of his decease was general peritonitis, lasting four days, supervening upon malignant disease of the gastro-hepatic omentum of a prolonged duration Dr Young was born in Brooklyn, educated at Fordham College, and a graduate from the College of Physicians and Surgeons, New York, in the class of 1854 He was for eight years connected with the Department of Health, as register of vital statistics or deputy commissioner, from which department his connection was severed about a year and a half ago He was forty years closely identified with, and served as secretary for, the Kings County Medical Society nearly ten years He also served that society in the capacity of vice-president He was a member of the consulting staff of St Mary's Maternity, and a member of several important social organizations Dr Young came of a family of physicians, several of his immediate progenitors having engaged in the practice of medicine He leaves a widow and three sons, the eldest of them being a physician

W S Youngblood, M D, of Groveton, Texas, October 6 ——D B Williams M D, of Louisville, October 6, aged 62 ——George W Stoddard, M D, of Ramsey, Ill, October 11, aged 33 ——T M Fettermann, M D, of San Antonio, Texas, October 6, aged 53

---

[1] Received at the Journal office, Oct 12 1895

PUBLIC HEALTH

Advice to Bicyclists —Rocheblave gives to bicyclists the following good advice from a medical standpoint 1, no one should ride until after an examination by a physician This examination should be made both before and after a walk or run, for some cardiac lesions only manifest themselves after a state of fatigue 2, ride no faster than 12 kilometers an hour 3, as far as possible guard against the desire to ride any faster It is very difficult not to give way to the "delirium of swiftness" With a light machine on a good road an amateur may easily make 25 kilometers an hour This is too much, for the pulse is increased to 150, even at 14 and 16 kilometers per hour[1]

Michigan State Board of Health.—The State Board of Health met in regular meeting, at Lansing, at 10 30 A M, Friday, October 11 Hon Frank Wells, president Hon A V Mc Alvay, Prof Delos Fall, Dr Samuel G Milner, Dr George H Granger, and Secretary Henry B Baker were present The regular business of auditing the bills and accounts was transacted Dr Milner, of Grand Rapids, offered the following resolutions, which were adopted by the board

Resolved, That hereafter the appointment of clerks in this department shall be in accordance with the principles of civil service, the service being classified if necessary, and appointments being made in each class by promotion for merit and length of service, or by examination, salaries to be graded according to class and term of service

Resolved, That the President, Secretary and one other member appointed by the President, constitute a committee who shall present the details of a plan in accord with the principles above stated

Dr Milner was appointed the other member of the committee Dr Cattermole was granted a leave of absence until April, 1896 One other clerk has gone to the University This made two vacancies in the office, and Mr Thomas S Ainge, of Detroit, and Sheldon B Young, of Lapeer County, were appointed to clerkships in the office

The Secretary presented the subject of reprinting some of the educational pamphlets which the office endeavors to distribute to the family and the neighbors of the person sick with a dangerous disease Several members stated that they believed these pamphlets and leaflets were of great benefit in the education of the people, just how to restrict and prevent each of the dangerous diseases The board were unanimously of opinion that these pamphlets of instructions should be reprinted in sufficient numbers to distribute wherever a communicable disease exists throughout the State The board authorized the Secretary to print 20,000 copies of the pamphlet relating to the restriction and prevention of diphtheria, 10,000 of the one relating to the restriction of consumption, and 10,000 of the leaflet relating to the restriction of typhoid fever The Secretary was directed to ascertain the best way to have the revised leaflets relative to diphtheria, typhoid fever and consumption translated for publication in the German and Holland languages

Secretary Baker presented a statement of the smallpox and typhoid fever in Michigan during the past quarter, and the present outlook for those diseases The Secretary's quarterly report of work in the office showed that more than the usual amount of work and considerable new and valuable work had been done One of the most important lines of new work was in connection with a 'blue letter" (official demand for reports, transmitting publications, giving information, etc) and with a final report to be used in collecting information tending to show the results of efforts for the restriction of consumption It is hoped that in consequence of these papers much valuable information will be received at the office of the Secretary

New work had also been done on a "final report" blank to be used in collecting information regarding the results of efforts in the restriction and prevention of smallpox in Michigan It is hoped that, through this series of questions, much valuable information will be received

An interesting letter from the Health Officer of Kalamazoo, was presented and read The letter is of special interest because it shows that Michigan is not behind in the most advanced public health work, it read as follows "In our present epidemic of diphtheria, which is clinically of a milder type than I have ever seen before, bacteriologic examination by a competent bacteriologist, who is paid by the city, is made in every doubtful case, especially so in the beginning when a strict diagnosis is hard to be made In the larger proportion of cases, antitoxin treatment has been used with good result To people who are unable to stand the expense, the city furnishes the antitoxin and the operator free of charge"

Secretary Baker presented reports from a few other cites, not in Michigan generally favorable to the use of antitoxin for diphtheria, and relative to the bacteriologic examinations, one report was from Rochester, N Y, which stated that through the bacteriologic tests, "many mild cases of diphtheria have been discovered which were formerly determined to be sore throat," and whereas such cases were formerly allowed to continue to spread diphtheria, they are now being restricted

A plan was presented for obtaining, through reports from health officers, a sectional township map of Michigan, exhibiting the residences of consumptives, for use in studying the parts of the State where the disease is most prevalent also for a study of the extent to which infected houses spread the disease, and the effects of disinfection of such houses Such permanent records may throw light on the origin of future cases of consumption in the same townships

Health Reports —The following health reports have been received by the Supervising Surgeon-General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Illinois Chicago September 1 to 30, 2 deaths
Louisiana New Orleans, October 10, 30 cases
Michigan September 28 to October 5, smallpox reported at Battle Creek, Bedford Township and Detroit
New York New York, October 5 to 12, 1 case

SMALLPOX—FOREIGN

Mauronillo (Cuba) August 1 to 31, 11 deaths
Santos September 7 to 14, 2 cases
Wigan (Eng) June 1 to October 1, 48 cases
London (Eng) September 21 to 28, 2 deaths
Dublin September 21 to 28, 2 cases, 2 deaths
Madrid September 20 to 27, 6 deaths
Moscow September 7 to 14, 1 case
Nogales September 28 to October 5, 1 case
Prague September 14 to 21, 4 cases
Rotterdam September 21 to 28, 3 cases
St Petersburg September 7 to 14, 2 cases, 2 deaths
Tuxpan September 21 to 28, 2 deaths
Warsaw September 7 to 14, 1 death

CHOLERA

Hiogo August 16 to 29, 1,266 cases, 927 deaths
Osaka August 16 to 29, 1,361 cases, 1,101 deaths
Honolulu August 9 to September 8, 58 cases, 44 deaths
Singapore August 19 to September 2, 22 cases, 11 deaths
Tarnopol September 10 to 15, 18 cases, 3 deaths
Tarnopol Des't September 11 to 15, 2 cases, 1 death
Zbaraz September 6 to 14, 2 cases, 1 death
Proskurow and Letelschew Districts August 21 to 31, 101 cases, 45 deaths
Constantinople September 10 to 20, cholera reported
Mossoul September 14 cholera reported.
Morocco, September 14, 11 cases, 12 deaths
Bombay September 3 to 10, 1 death
Cognac September 21 to 28, 1 death
Yokohama August 23 to September 6, 27 cases, 19 deaths
Nagasaki September 4 to 10, 20 cases, 16 deaths

YELLOW FEVER

Mauronillo August 1 to 31, 23 deaths
Acapulco September 14 to 21, 1 case, 1 death
San Juan P R September 1 to 21, 22 cases, 6 deaths
Santiago de Cuba September 21 to 28, 19 deaths
Vera Cruz September 26 to October 3, 4 deaths

---

[1] L'Union Medicale 1895, No 32

MISCELLANY

Treatment of Typhoid Fever.—Dr John Eliot Woodbridge, whose articles on typhoid fever have frequently appeared in the columns of the JOURNAL, has been in Chicago for the past two weeks, treating cases of typhoid fever in the hospitals of Chicago, and superintending the issue of his new book on the "Treatment of Typhoid Fever" which is now passing through the press

Exemption from Taxation of Farms used for Hospital Purposes—Farms bought and used for hospital purposes, as a part of the hospital plant, an open air sanitarium, and roaming ground for manageable and convalescent patients, very much as a playground might be used as an aid in the cure of sick children, the Supreme Court of Pennsylvania holds, in the case of Contributors to Pennsylvania Hospital v Delaware County, decided July 18, 1895, are exempt from taxation That they are also farmed for profit to reduce expenses, the court maintains, does not vary their position as part of the plant, though if there were any fair doubt of the good faith of such use, the case would be different Property which is not used directly for the purposes and in the operation of the charity, but for profit, is not exempt, and the devotion of the profit to the support of the charity will not alter the result It is, however, not material that such farms are separated from the main hospital building, and not used with it, nor that their use for hospital purposes is limited to the months of pleasant weather, in the summer and autumn

Successful Ligature of the Innominate Artery—A man was recently on exhibition in London whose innominate artery was tied by Mr Coppinger, at the Mater Misericordiæ Hospital in Dublin, in January, 1893 The operation was for the relif of aneurysm of the subclavian artery He was exhibited shortly after the operation in Dublin and later at Newcastle on-Tyne The man is 50 years of age and is in excellent health It is claimed for him that he is the only living example as yet exhibited in Europe of cure of subclavian aneurysm by innominate ligature —*N Y Med Record*

There is one case to our knowledge walking the streets of St Louis in perfect health whose innominate artery was successfully ligated in 1892 by Prof Waldo Briggs, of the St Louis College of Physicians and Surgeons —*St Louis Clinique*

Concerning the Action of the Diphtheria Antitoxin on the Kidneys and on the Heart—C V Kahlden (*Centralbl für Allg Path u Path Anat* Band vi, Nos 3 and 4) made the following experiments in order to determine whether or not the diphtheria antitoxin has any special effect upon the heart or upon the kidneys He injected guinea pigs and rabbits with very large quantities of serum as compared with the body weight of the animals and then after one or more injections the animals were killed and the kidneys and the heart muscle examined microscopically, after fixing and hardening according to the most approved methods There were no changes of any kind to be found, either in the kidneys or in the heart muscle V Kahlden is not prepared to say from the results of these experiments that the serum might not aggravate the morbid process often present in the kidneys of human diphtheric patients as the result of the elimination of the toxic products of the diphtheria bacillus, but direct anatomic evidence of such an effect is still lacking

All Massachusetts Cities Must Have Boards of Health.—The former Massachusetts statute providing that in each city, except Boston, in which a majority of the voters shall have so voted according to law, there shall be a board of health, consisting of the city physician and two persons, not members of the city council, whose term of office shall be two years, has been superseded by a new enactment which provides that in each city, except Boston, there shall be appointed by the mayor, subject to confirmation or rejection by the board of aldermen, except where other provision is made in the city charter, a board of health, consisting of three members, who shall hold office for the term of three years, one of whom shall be a doctor of medicine

Liability of Boards of Trustees in North Dakota—A law has been passed in North Dakota making any board of trustees, commissioners, directors, person or persons having the control or management of public institutions of the State, or having in any manner whatsoever the responsibility of disbursing or expending any money appropriated by the State, who, either directly or indirectly, expend or agree to expend, for the benefit of any institution or purpose, any amount in excess of the sum appropriated therefor, or who uses or transfers any appropriation to another purpose, conjointly and individually liable for all amounts so used or transferred, and forfeits his or their offices However, when an emergency arises requiring it, the Governor, Secretary of State and State Auditor may be appealed to, as a commission with power to authorize the transfer of money from one fund to another fund, of the same institution or purpose, or to authorize money therefor to be drawn from the State treasury Much the same end is sought to be reached in South Dakota by a somewhat different law

Changes Involving Massachusetts Town Boards of Health—Chapter 506, of the Acts of 1895, provides that every town in the commonwealth of Massachusetts may elect a board of health by ballot at the annual meeting of the town, or at a meeting legally warned for the purpose, consisting of three persons, to serve, one for the term of three years, one for the term of two years and one for the term of one year, beginning with the day following such town meeting or until their respective successors are chosen and qualified, and thereafter such town shall, at its annual town meeting, choose in the same manner one person who shall hold office for three years from the day following such town meeting or until another is chosen and qualified in his stead If no such board is chosen, the selectmen shall constitute such board of health So much of the Act of 1894 as provides that one member of the board of health shall be a physician, shall not apply to towns in which the selectmen constitute the board of health Those persons chosen by ballot and declared elected as members of the board of health of any town at its annual, or any special, town meeting prior to the passage of this Act, shall constitute the legal board of said town, notwithstanding any informalities or defects in the proceedings

Larvated Tuberculosis of the Tonsils—Dieulafoy (*La Semain Medicale*, 1895, p 199) injected pieces of human tonsils into guinea pigs Of sixty one animals so treated eight became tuberculous, i e, 13 per cent Of thirty-five animals inoculated with adenoid masses from the tonsils, seven became tuberculous, i e, 20 per cent From these results the author concludes that the various tonsils are the place of entrance for the tubercle bacilli in a considerable number of instances, and that the tuberculosis gradually spreads to the lymphatic vessels, the glands of the neck and then to the lungs In order that tubercle bacilli may lodge in the tissue of the tonsils only a small lesion of the epithelium would be necessary, and such lesions are certainly present often enough

Fat Embolism after Forcible Flexion of Both Knee-Joints—F Colley (*Dtsche Zeitschrift f Chir*, Bd 36) describes a very unique case of extensive fat embolism following *brisement forcé* of both knee joints without injury to the bones The patient, a 24-year-old girl, died twenty-four hours after the operation The fat embolism was very marked in the lungs the brain, the kidneys, and especially in the heart muscle In the heart there was a focal fatty degeneration of the muscular fibers around the capillaries that were filled with fat. This myocardial degeneration undoubtedly played a principal part in bringing about the fatal termination The source of the fat embolism was, undoubtedly, the markedly fatty vasti muscles of the thigh, which were lacerated during the operation

"Malignant" Lymphoma—Fischer (*Deutsche Zeitschrift f. Chirurgie*, Bd 36) describes two cases of malignant lymphoma with the post-mortem findings In the first case there were lymphomatous formations in the internal organs but no tuberculosis or suppuration Clinically, this case was marked by periodic attacks of fever lasting ten to twenty-one days with free intervals of about the same length Fischer showed that this fever depended on infection with the staphylococcus pyogenes which was present in the blood and the lymphatic gland juice during the period of pyrexia, but absent in the intervals of normal temperature Post-mortem, no microörganisms were found in the glands In the second case there was an extensive lymphomatous growth in the neck, in the axillæ and in the inguinal regions with tuberculous ulcers of the intestine, tuberculosis of the bronchial glands and of the lungs but the cervical lymph glands showed no bacilli, and no histologic changes characteristic of tuberculosis Inoculation with pieces of the gland into the peritoneal cavity of pigs was not followed by the development of tuberculosis and, consequently, Fischer regards the tuberculous lesions in this case as the result of an infection independent of the lymphoma

Football Casualties —A serious casualty has already been reported as a file-leader for the series of football accidents in the season of 1895–96 An animated contest on a New Jersey field resulted in the laying up of a junior player He was tripped while running, and was fallen upon heavily by a number of other players, his ankle and two or three ribs were fractured His ultimate recovery is expected A dislocation of the femur was treated in Professor Hamilton's clinic, Chicago October 12 The patient belonged to the team of one of the high schools on the West Side A press dispatch reports the death of a football player from an accident received while playing at a western college

The Index Medicus —The following circular has been issued

PHILADELPHIA, Oct 1, 1895

Dear Doctor —The *Index Medicus*, as you doubtless know, has ceased to exist, because the number of subscribers was not sufficient to pay for its publication Its value was so great that the undersigned, a self constituted committee, have concluded to appeal to the literary workers of the medical profession to unite in reviving it The nature of the *Index* is such that it can never obtain a large subscription list, but it is invaluable to those engaged in literary research It will require about $5,000 annually to publish it The former editors are willing to take up the work again if 200 subscribers at $25 per year can be obtained We have each agreed to subscribe for a period of five years, will you not do likewise, and mail accompanying blank, duly signed, to the Secretary of the Committee? If the term seems too long, will you not fill in the blank for three or less years? The Committee also begs you to get as many of your friends as possible to subscribe, and to send to the Secretary the names of any persons, society or library likely to become a subscriber Yours truly,

WILLIAM PEPPER, J WM WHITE,
S WEIR MITCHELL W W KEEN
H A HARE, GEO M GOULD,
DEF WILLARD, JOHN H PACKARD,
J C WILSON, E LAPLACE,
H C WOOD,
1627 Walnut Street JOHN B ROBERTS, Secretary

Influence of Season on Insanity —Dr Forbes Winslow has furnished the New York *World* a popular article on insanity in women, in the course of which he discusses "the influence which the seasons exert in producing insanity in females" Analyzing the statistics of a large hospital for a period of twenty-two years, during which a total of nearly 5,000 patients—2,955 females and 2,019 males—were treated, it is shown that during the first quarter of the year—the months of January, February and March—the number of females received amounted to 649 In the second quarter of the year—April, May and June—842 were admitted In the third quarter—July, August and September—798 was the number, and in the last quarter—October, November and December—the admission of insane women amounted to 668 It is seen, therefore, that a much larger number of insane women were admitted during the second and third quarters —in spring and summer—than in any other period of the year On the other hand, most cures were effected in the fourth quarter, while most deaths occurred in the first quarter of the year On an analysis of each month taken individually, the greatest number of female curable lunatics were admitted in May and the smallest in January Less females were discharged cured during the early part of the year than in any other part of it, and most deaths occurred in the months of January February and March and the least in April May and June From these data Dr Winslow says "We may rationally conclude that, as the temperature of the weather diminishes and the year draws to a close, so may we form a more favorable opinion respecting the prognosis in cases of insanity in women On the other hand, seeing that insanity is so much more prevalent in summer than in winter every exciting cause, whether physical or moral, ought to be carefully guarded against in the former season, especially in those women who are in any way liable to, or in whom has been developed any previous attack"

The Allen Medical Library —In answer to a correspondent, we have to say that books and pamphlets intended for the Allen Medical Library should be sent in care of the Presbyterian Hospital, Chicago

The library was donated about ten years since by the late Prof J Adams Allen, of Rush Medical College, and the Superintendent, Dr Stehman, was designated as the Librarian It has by reason of the additions to the original collection, grown to be a fairly comprehensive medical library, and is of considerable value No printed catalogue has been issued

Suppression of Urine After Operation—Saline Injection—Recovery —Dr Charles McBurney has reported to the New York Surgical Society a case of the above nature that was successfully treated by saline infusion This case has been published in the August issue of the *Annals of Surgery* The operation was for the removal of a large calculus from the right kidney, in a male patient aged 50 years The saline infusion that appeared to reëstablish the renal function was in quantity about one quart, and was injected into a vein in the arm The following is a part of the report 'The operation of the kidney was attended with only moderate bleeding, no ligature and no packing was required for its control In the course of the twenty-four hours next following the operation nausea began and was soon followed by vomiting, headache, and symptoms of uremic intoxication There was no voluntary discharge of urine, and only one half ounce was obtained by catheter during the first twenty-four hours after the operation The saline infusion, above referred to, was followed in the course of a few hours by the discharge of thirty-five ounces of urine The patient thereafter steadily recovered In the discussion of this case that followed, reference was made to a case of total suppression of urine after an operation for gangrenous hernia, in which striking improvement had followed similar treatment It was also called to mind that Dr Howship Dickinson had in the *British Medical Journal* called attention to the fact that patients could be aroused from diabetic coma in a few minutes by saline infusion

Some Centenarians and Others —Dr Charles E Rice, of Alliance, Ohio, held his second annual old folks' reception at his residence in that city on the 27th ult, at which were four centenarians—all women, by the way—and some eighty other guests whose ages ranged from 72 to 103 years Mrs Elizabeth Byers, aged 103, drove twenty-four miles in a buggy to attend the party, and brought and used the spinning-wheel that she has owned for eighty years Mrs Priscilla Spooner, the next in wealth of years, was *born in Duxbury, Mass*, Dec 11, 1793, the daughter of Capt Judah Delano Mrs Catherine Hoobler, born in Loudon County, Va., in 1794, is the great-great-grand aunt of Dr Rice Mrs Letitia L Walker was born near Shippensburg, Pa., *in* 1795 There were also present among the women one each aged 97, 95, 94

91, 88, 87, 84 and 83 years, and two each aged 89 and 86 years The oldest man was 99, and there were one each aged 96, 94, 93, 91, 88, 87, 86, 84 and 82 years, two aged 92 years and three aged 90 years each The aggregate ages of the sixteen women—83 to 103 years—was 1,475 years, being an average of 92 2 years each, the aggregate ages of the fifteen men—82 to 99—was 1,354 years, being an average of 90 3 years each Obviously the New Woman is not enjoying a monopoly of superiority over masculinity Elizabeth and William Ware, aged respectively 91 and 90 years, have been married more than sixty years and were the oldest married couple present, and the oldest physicians were Drs Josiah Beebout, 92, and John P Gruwell, 86 years The oldest soldier was James R Green, born in Bolton, England, in 1796, who addressed the students of Mount Union College in his ninety-ninth year, on the 18th of June last, the eightieth anniversary of the battle of Waterloo, in which he participated Mrs Nancy McKinley, aged 86, mother of ex-Gov William McKinley, was also present

Neuralgia Cured by Resection of the Eighth Cervical—Mm Chipault and Demoulin report a very interesting cure of cervical neuralgia A man of 38, otherwise in good condition, had for four years suffered from a continuous pain localized in the little finger and inner part of the hand, with exacerbations shooting along the inner border of the forearm He had been submitted to all sorts of remedial measures without relief, among others, stretching the dorsal cutaneous branch of the ulnar and section of the same in the epitrochlear fossa When he came under the author's observation examination showed that the hyperesthetic zone comprised the inner surface of the little finger with the corresponding part of the hand and two strips on the arm and forearm, one and one-half centimeters wide—one anterior, the other posterior From the researches of one of the authors it is proved this is the exact area of cutaneous innervation from the eighth cervical It was therefore decided to open the spinal canal After resection of the vertebræ nothing abnormal was found in the spinal canal nor in the intervertebral foramina The dura was then laid open and the posterior root of the right eighth cervical with the nerve above and below, was resected between the ganglion and the cord These adjacent nerves were resected also, because physiology teaches that section of a single root is insufficient to anesthetize its territory Two hours after the operation the zones of hyperesthesia and spontaneous pains had disappeared The patient was able to use his hand for eating soup and for writing, which had been impossible for years on account of pain Four months after the operation the recovery still persists with no consecutive trophic troubles On the contrary, those remaining after the resection of the ulnar nerve have disappeared Some interesting physiologic manifestations were noticed during and after the operation, among them—electrical stimulation of the posterior roots produced a manifest vaso constriction in their territory The resection of these three roots caused only a slight hyperesthesia of the arm, which disappeared in twenty-four hours[1]

Bacterial Examinations of the Throat in Fevers other than Diphtheria—At the London Fever Hospital, Dr J O Symes, an assistant medical officer, has for a year made examinations of the throat in all cases admitted to that hospital, wherein an exudate was seen in the fauces, and the summary of his finding is given in the London *Lancet* for August 24

"Cultivations have also been made from time to time from throats presenting no abnormal appearances As a rule, the cultures were taken upon admission, but some after a stay of from two to eight weeks in the wards A sterilized swab of cotton wool upon a rod was passed lightly over the fauces and tubes of blood serum inoculated from this The publication of a brief summary of the notes of the first 100 cases so examined may be of interest at the present time, in view of the increased attention paid to the bacteriology Bacteriologic examinations were made of exudations from the throats of 68 patients suffering from scarlet fever, 52 were made on the day of admission, 8 during the first seven days, and 8 at periods varying from the third to the eighth week Of these cultivations 14 showed pure streptococci, 25 streptococci and cocci in groups, 2 cocci in groups, 1 cocci and the long variety of diphtheria bacillus, 9 cocci and the short variety of diphtheria bacillus, 14 cocci and other forms of bacilli and 3 showed various forms of bacilli only The bacillus most frequently found was a short stout variety with a central non-staining portion It was arranged in chains or groups, and liquefied serum in from three to six days"

The case of scarlet fever in which the long variety of diphtheria bacillus was found made a good recovery, and was not attended by any paralysis In one of the short bacillus cases there was a paresis, also anesthesia of the palate Certain cases, 8 in number, that were sent to the hospital, certified to as diphtheria, were not found to develop the Klebs-Loffler bacillus, assumed the characteristics of scarlet fever or tonsillitis, one case which had much faucial exudation proved to have a well-marked attack of typhoid fever Fourteen cases of measles, some of which had exudate in throat, were cultivated Colonies of the short bacillus were found in 7 cases Pure cultures were not virulent to guinea pigs The long variety was found in none of these cases In 18 cases admitted as diphtheria, the long variety of bacillus was found in 10, in one case there were colonies of the long and short varieties The short bacilli were demonstrated as present in the throat twelve weeks after admission A pure culture of the latter was not virulent to the guinea pig In one case the long bacilli were present in the sixth week, this being the longest period of the persistence of this variety that was noted by Dr Symes

Relations between Malignant Tumors and Traumatism—Ziegler of Munich, assistant in Angerer's clinic, has published an interesting paper in which he seeks to determine if traumatism is one of the factors in the etiology of malignant growths He divides his cases into *a*, carcinomata and *b*, sarcomata *A*, carcinomata 328 cases were observed, 117 in males, 211 in females In fifty-five cases there was a history of traumatism and in ninety-two cases a history of chronic irritation As regards mammary carcinoma in females, which numbered 170 cases, 37 had a traumatic history The following table gives the results of other investigations

Estlander	59	cases,	trauma	15
Snow	143	"	"	32
Bihler	40	"	"	8
Henry	146	"	"	15
Rapok	89	"	"	13
Sprengel	131	"	"	19
S Wolff	108	"	"	10
Horner	158	"	"	14
Oldecop	250	"	"	18
Winiwarter	170	"	"	12
Schulthess	58	"	"	2
Fischer	63	"	"	1

The influence of traumatism on the development of carcinoma of the lips appears clear Thus, of forty-four tumors occupying this region, forty-two were situated on the upper lip and only two on the lower, on the other hand, thirty-five occurred in men and only seven in women Traumatism is more frequent in the upper than in the lower lip, and men are manifestly more exposed In this respect the statistics of other authorities corroborate those of Ziegler Concerning the influence of antecedent traumatism on other regions, it seems less clear for other parts of the head—buccal cavity, maxillary region, parotid, etc, on the other hand, it seems that phimosis and the irritations resulting from it play a certain rôle in the development of carcinoma of the penis Of nine carcinomas of the limbs, all developed under the apparent influence of a chronic state of irritation In this connection the author recalls Volkmann's statistics—228 cases of carcinomatous tumors of the limbs, 98 of which developed as a result of a chronic inflammation of the skin, 32 from ancient fistulas, 11 in connection with congenital warts and 12 with acquired warts *B* Sarcomata Of 171 cases of sarcomatous tumors, 81 occurred in men, 90 in women

---

[1] L'Union Medicale, 1895, No 82

There was a history of traumatism in thirty-five cases, and of chronic irritation in thirty two cases. Thus, of 400 cases of carcinomatous and sarcomatous tumors, in 90 there was a history of antecedent traumatism and in 124 of chronic irritation. Ziegler is of opinion that the results of his inquiries prove indisputably that traumatism is a factor in the etiology of malignant neoplasms.[1]

Increase of Venereal Disease in the British Army.—In the *Lancet*, June 29 appears a statement concerning an apparent increase of venereal disease in the British army, due to the abolition of the acts known as the Contagious Diseases Acts. The *Lancet* takes for its text a communication which was read at a meeting of the Académie de Médecine in Paris on May 21 last by Dr. Commenge. The documents furnished in England by the Minister of War, said the speaker, have brought the gravity of the case into prominent relief. In 1892, out of 196,336 soldiers 52,155—that is to say, *upward of a quarter of the entire British army*—were admitted to hospital on account of venereal disease.

"In the opinion of the majority of army medical men this extraordinary development of the venereal diseases is with justice to be ascribed to the abolition of the Contagious Diseases Acts, and even the late Dr. Graham Balfour, who was for a time opposed to the regulation of prostitution, changed his views on this point. It will be interesting to draw a comparison, continued Dr. Commenge, between the existing state of affairs in England, where prostitution is free, and that obtaining in France, where, happily, some proscriptive measures still remain in force. In 1875, the year that venereal diseases were most prevalent in the French army, the number of cases was equal to 74.5 per 1,000 of strength, during the same year in England the proportion was 139.4 per 1,000. The highest rate in the British army is referable to the year 1885, and amounts to 274.4 per 1,000, in the French army that year the numbers yield 52.1 per 1,000 only. When we examine the returns in order to ascertain the prevalence of syphilis, the following are the results: in the French army the worst year for syphilis was 1875 when the proportion of cases was 11.3 per 1,000 of strength. In the British army during the same year it was 28.8 per 1,000, and in 1887, when the highest ratio was reached, it was 46.6 per 1,000. In France during the latter year the syphilitic rate was only 8.9 per 1,000. Dr. Commenge has, moreover, made a study of the sanitary condition of the Russian army, where venereal affections maintain about the same level that they do in the French army, save that syphilis is slightly more prevalent. Needless to say, prostitution in Russia is under the control of the authorities. The relative prevalence of venereal disease in the three armies is shown in the subjoined table, the figures giving the cases per 1,000 of strength.

	England	France	Russia.
1889	217.1	45.8	40.7
1890	212.4	48.8	48.0
1891	197.1	48.7	41.5
1892	201.1	44.0	44.6

"The following table shows the comparative prevalence of syphilis alone.

	England	France	Russia
1889	85.7	9.1	12.9
1890	87.8	9.1	18.4
1891	82.2	8.9	12.2
1892	83.8	9.2	18.7

"Dr. Commenge next extended his investigations in order to determine the sick rate in the several divisions of the French army, and found that the incidence of venereal disease was largely influenced by the presence or absence of clandestine prostitution in the various garrison towns. Paris, Algeria and 'the Midi' were notorious centers of illicit intercourse and it was in these districts that the venereal rate invariably attained its maximum. Dr. Commenge brought forward a formidable array of facts and figures in support of his thesis, which was pronounced to be an eminently interesting and instructive work. His conclusions are three in number. 1, venereal diseases are always far more numerous in countries where there is free trade in prostitution than in those where regulations are in force, 2. the regulation of prostitution serves to attenuate the virulence of the venereal diseases and to hinder their progress, 3, the results now adduced are in accordance with the resolutions of the Académie de Médecine voted in 1888, when the attention of the authorities was drawn to the dangers of prostitution and to the necessity for safeguarding the public health."

Philadelphia Notes.

Dr. Thomas J. Mays on the 9th inst. read a paper before the County Medical Society "On the Local Application of Ice in Acute Pneumonia," which was the second collective report upon this subject presented by him to this Society. In June, 1894, he had given the statistics of 50 cases and the present paper brings up the total to 195 cases. Among this number there were seven deaths—four male, three female, a mortality rate of 3.58 per cent. The cases ranged from three weeks to 75 years of age. Sex was noted in 143 cases, of which 67 were males and 76 females, which is contrary to the general observation. There were 108 cases of single, and 31 cases of double pneumonia (or about 30 per cent.), these furnished three out of the seven deaths (over 40 per cent.). The results of the ice treatment were very obvious: 1, in relieving pain, 2, reducing pyrexia, 3, alleviating symptoms, 4, shortening the course of the disease and hastening the day of the crisis, 5, lowering mortality rate, and 6, increasing the patient's comfort. The results of the ice bag treatment, as compared with other methods, were pronounced to be infinitely more satisfactory than the latter. In more than 15 per cent. of the cases, the crisis appeared on the second day, and in 53 per cent., it occurred on the fifth day. The symptoms of pneumonia are regarded by Dr. Mays as expressions of a disorder of the nervous system through the vasomotor nerves. In this connection Hughlings Jackson's remark that he regarded acute pneumonia "as a form of herpes zoster of the pneumogastric nerves" was quoted, as well as Fernet's statement, that "so called fibrinous pneumonia is a herpes of the lungs." In addition to the application of the ice bag (almost constantly, or with brief remissions) Dr. Mays gives strychnin to sustain the heat and pulmonary innervation, digitalis, morphin and brandy, and resorts to oxygen inhalations, strapping of chest in case of pleuritic pains and an ice bag to head to diminish restlessness.

Dr. M. V. Ball at the same meeting reported 'A Case of Acute Cocain Poisoning." A woman, 35 years of age, swallowed 25 ccm. of a 5 per cent. solution, equal to about 1¼ gm. (18½ grains) of the alkaloid. Intoxication, restlessness and delirium of a maniacal character rapidly supervened. The mouth and throat were dry, the pupils dilated, the teeth gritted in a tetanoid manner, and she talked incessantly. Pulse 140, temperature normal, no general anesthesia. Morphin hypodermically, black coffee, and afterward strychnin were given by the mouth, also alcoholic stimulants. Two hours after onset of symptoms, the patient was quieter, pulse stronger but still rapid. On attempting to walk, legs were found to be almost useless, the symptoms gradually passed off. The fact that the patient had been accustomed to using cocain for a painful disease of the rectum, may have had something to do with the recovery. On a previous occasion she had, by mistake, taken a poisonous quantity of the alkaloid in a dry state, followed by active delirium, and recovery under the free use of morphin.

Dr. Harrison Allen, at the October meeting of the Laryngological and Otological Section of the College of Physicians, made some remarks upon the anatomy of the temporal bone. He doubted the propriety of the ordinary division into squamous, petrous and mastoid portions and said that the latter portion has a smaller extent and a less consequence than is usually stated in the text-books. The squamous portion extends behind the auditory opening and occupies the anterior third of the so-called mastoid portion. Thus we have (in relation to the auditory canal), a pre-squamous, and a post-squamous, the post-squamous containing the large air-cells and frequently contains all that are in this region having the mastoid portion dense, like the remaining part of the petrosal division. A line of suture can usually be traced on the outer surface of the mastoid, which divides it in front from the post-squamous portion. For the portion surrounding the internal ear, Dr. Allen proposes the name of peri otic so as to make it uniform with the nomenclature of comparative anatomy. The upper portion of the peri otic portion, on its external surface presents some irregular markings produced by blood vessels, and for this locality the name "serpiginous portion" of the peri otic temporal bone is proposed. One point of interest from a clinical standpoint is that operators are requested to examine their cases closely and to state whether the abscess or operation in this region is entirely anterior or posterior to the squamos peri otic suture, in the interest of accuracy of definition.

Dr. Oscar H. Allis, at the Academy of Surgery meeting on the 7th inst, reported a case of gastro enterostomy for malignant disease, in which a Murphy's button was retained in the stomach for sixteen months and was found there at the autopsy, it having occasioned no special symptoms during life

---

[1] La Medicine Internationale, 1895, No. 7.

THE MEDICAL CLUB tendered a reception to Prof Wm H Welch, of the Johns Hopkins University, on the 16th inst, at the Hotel Bellevue, which was largely attended by the leading members of the profession of this city and vicinity

PROF J M DACOSTA has returned from Europe entirely recovered from the effects of former illness and now in excellent health The eighth edition of his work on "Diagnosis" has just been issued He resumes his clinical lectures at the Pennsylvania Hospital on November 1

THE RUSH HOSPITAL FOR CONSUMPTIVES has removed to 33d Street, above Lancaster Avenue, the new hospital being opened with a high tea by the Woman's Board The site was purchased some time ago, and is admirably suited for the purpose, being on high ground and with abundant open spaces around it It will be extended as funds are accumulated, one wing to be built at a time

Society Notes

DETROIT MEDICAL AND LIBRARY ASSOCIATION —The annual meeting of this Society was held Monday evening, October 7 The following officers were elected for the ensuing year President, Ernest T Tappey, Vice-President, Chas W Hitchcock, Secretary, Willis S Anderson, Treasurer, Anderson P Biddle After the business session the retiring President, Dr Eugene Smith, tendered a reception to the members

AT THE first annual meeting of the Utah State Medical Society the following officers were elected President, Walter R Pike, Provo, First Vice-President, G W Perkins, Ogden, Second Vice-President, J S Richards, of Salt Lake, Secretary, J N Harrison, Salt Lake ——The annual meeting of the Cedar Valley Medical Society was held October 8, at Waterloo, Iowa The following officers were elected for the ensuing year President, Amos G Shellito, Independence, Vice-President, J F Cole, Oelwein, Secretary, W B Small, Waterloo The next meeting will be held in Dubuque —— The regular semi-annual meeting of the Upper Cumberland Medical Society was held at Cookeville October 2 The semi annual election of officers resulted as follows President, J L Jones, New Middleton, Vice President, J F Dyer, Cookeville, Secretary, W J Breeding, Sparta, Treasurer, L R McClain, Cookeville ——The regular quarterly meeting of the Clinton County Medical Society was held at Clinton, Iowa, October 1 ——The Miami Medical Association held its sixty sixth annual session at Lockland, Ohio, October 8 Papers were read by Drs R T Trimble, New Vienna, Arthur L Knight, Madisonville, J M Scholler, E G Zinke, R B Hall, W H Taylor, J J Bonar, J C Oliver and B P Goode, Cincinnati, Percy M Ashburn, Batavia, and B H Blair, Lebanon ——The Northwestern Wisconsin Medical Association held its quarterly meeting at Wausau, Wis, October 8 ——The Eastern Kansas Medical Society met in Topeka, October 8

Louisville Notes

ACADEMY OF MEDICINE —The regular meeting of this society was held in their rooms Monday, October 14 Dr R A Bates read the paper of the evening on "Hypertrophic Cirrhosis of the Liver" The discussion was opened by Drs J B Marvin, F C Wilson, and John Barbour

PHYSICIAN'S WITNESS FEES —Judge Toney, in the Law and Equity Court, decided a disputed point which is of interest to all physicians In a damage suit, Dr B F Atchison was summoned as a witness for the plaintiff He was not present when the case was called and the plaintiff refused to go into the trial without him, requesting an attachment returnable forthwith The court refused to issue the attachment, and the plaintiff then had the case dismissed without prejudice Judge Toney said the plaintiff had not agreed to pay the physician's fees and expenses, and therefore could not force him to appear in court, although he had been subpœnaed He said the law on this subject is an old one, although it had never been enforced To compel the attendance of a physician it is first necessary for the party desiring his evidence to pay his fees and costs, and Judge Toney said that he would compel no physician to attend his court under any other circumstances

WITHERSPOON —Central Kentucky has sustained a great loss by the death of one of the most prominent younger physicians of that section Dr John T Witherspoon has been ill for several weeks of typhoid fever, at his home in Lawrenceburg, in the heart of the blue grass section, his illness assumed a grave aspect a few days ago and he died October 11 He was in his twenty-fifth year, was graduated from the University of Louisville, in 1892, and was the son of Louis Witherspoon, President of the Anderson Deposit Bank He was prominent in local masonry, by which order he was buried

St Louis Notes

THE ST LOUIS MEDICAL SOCIETY —At the meeting of October 12, the discussion of the application of the toxin of erysipelas in the treatment of sarcoma, was the feature of the evening, the subject having been introduced by Dr George Halley of Kansas City

THE ST LOUIS CHILDREN'S HOSPITAL —A bequest of $6,000 made by the late Robert A Barnes to this institution, is now about to come into the hands of the hospital authorities as a result of an amicable suit A change in the name of the institution and the death of the trustee named in the will of Mr Barnes were the cause of delay in the delivery of the funds

THE REBEKAH HOSPITAL TRAINING SCHOOL FOR NURSES will hold its second Commencement October 22

DIPHTHERIA —The teachers in the public schools are now required to send home all children manifesting any symptoms of sore throat The energetic efforts of the Board of Health to restrict the spread of diphtheria are thus receiving coöperation, and success seems more and more assured

MARION-SIMS COLLEGE OF MEDICINE —The dental department of this college has opened its second year with forty two students

THE WOMAN'S MEDICAL COLLEGE has begun the college year with greatly increased facilities The new regulations of the State Board of Health caused the rejection of eight applicants for admission, but this has had no effect on the prosperity of the college

DR CHARLES FINLEY HERSMAN died October 11, of nephritis At the time of his death he was professor of clinical medicine in the Missouri Medical College Dr Hersman was justly esteemed one of the most brilliant and promising of the younger members of the profession of St Louis His advancement had been rapid and was due entirely to his learning and practical attainments His career, characterized throughout by the greatest modesty, is the more remarkable from the fact that he was but too well aware that he was suffering with an incurable chronic malady which would certainly prevent the fruition of his labors He had undertaken a large increase of clinical work which probably had some influence in hastening his death He will be sadly missed by his colleagues in the faculty

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from October 4, 1895, to October 10 1895

PROMOTION

Major William E Waters, Surgeon, to be Deputy Surgeon General with rank of Lieutenant Colonel Oct 1, 1895, vice Billings, retired

Capt Louis S Tesson, Asst Surgeon, to be Surgeon with the rank of Major Sept 26 1895, vice Matthews, retired

Capt Edwin F Gardner, Asst Surgeon, to be Surgeon with the rank of Major, Oct 1, 1895, vice Waters, promoted

ADDRESS

INTRODUCTORY ADDRESS

Delivered September 30 at the College Building, Georgetown University, District of Columbia

BY GEORGE M STERNBERG, M D
SURGEON GENERAL U S ARMY
WASHINGTON, D C

Ladies and Gentlemen —The Faculty of the Medical Department of Georgetown University has decided upon a new departure in medical teaching in the District of Columbia, and by their invitation I am here to deliver an address upon an occasion which they very properly consider to be one of unusual interest to the medical profession and to the citizens generally in this great and rapidly growing capital city Heretofore the courses of instruction have been so arranged that students who are occupied, during the official hours, in the various government offices located in this city could take advantage of them This has no doubt made it possible for many industrious and deserving men to obtain the degree of Doctor of Medicine who would otherwise have been unable to do so And I presume that a fair proportion of those who have pursued their medical studies under these circumstances have become successful practitioners of medicine, while others have been satisfied with the title of Doctor, and have, wisely perhaps, held on to the salaried position which enabled them to secure their medical degree While this system has no doubt been advantageous to many worthy young men, and has supplied the ranks of the profession with a certain number of well qualified practitioners who have risen to prominence in their chosen profession, it is generally admitted that it does not give the best possible results There is something to be said, however, for the class of men who have taken advantage of it The fact that they have been able to secure a government position may be taken as evidence that their English education is better than that of very many of those who obtain a medical degree elsewhere, and their industry is made evident by the fact that they are able to pass creditable examinations at the end of their course, although the best part of each day is, or should be, spent in the more or less exacting duties for which they receive a salary from the government

My experience as a member of Army Medical Examining Boards leads me to the conclusion that very many of those who receive degrees from medical colleges, in all parts of the country, would utterly fail to pass the civil service examination required of clerks in the government service The mistakes in orthography, grammar and literary style made by a considerable number of the candidates for admission to the Medical Corps of the Army are lamentable and sometimes amusing It is said that a Navy examining board on one occasion rejected a candidate for spelling Philadelphia with a small f Certainly no amount of medical knowledge, at the present day, will enable an illiterate man to maintain the respect and confidence of educated people The man with a defective medical education may impose upon his non-professional fellow citizens, and if he has an agreeable address and an elastic conscience may become a successful practitioner—if success is to be measured by the number of his patients and the extent of his income But a defective English education is something that reveals itself, sooner or later, to the educated classes, among whom a physician with a reasonable degree of ambition and self esteem would naturally hope to practice

A recent editorial in a leading medical journal (*The Medical News*) refers to the importance of correct English orthography as follows "There can be no question that men have shown ability to do good intellectual and social work of undoubted value to civilization who could not spell ten words correctly But, and here's the rub, that day is either past or should be past It is by every one admitted, and by none more fully than by the combined good physician and poor speller, that without the preliminary education, evidenced at least by correct spelling of one's native language, the modern physician is now and henceforth not only handicapped, but utterly outclassed in the race of life It is not that knowledge of spelling will make one the better physician, but the lack of that knowledge certainly gaurantees other lacks that squarely debar from the higher education essential at this day It has been said that without money, or a certain amount of it, one can not get what money alone can not buy, and it is much the same with preliminary education "

The editor appends to his article a list of 120 misspelled words which he says, "is culled with exact spelling from the papers of those examined by the Board of Medical Examiners representing the State Medical Society of Pennsylvania " I select a few examples from the list given Apatite, Assleep, Alsow, Boath, Fatial (facial) Hedacke, Jerms, Ulser (ulcer), Sudent (sudden), Skinn (skin), Sower (sour) Comment is unnecessary, but we may remark that the examiner who furnished the list referred to, to the editor of the *Medical News*, says that "some of these gentlemen were graduated this year by medical colleges in Philadelphia "

This illiteracy of graduates in medicine is not limited to any section of the United States, and a presidential address recently delivered by a distinguished English physician indicates that the evil is not limited to this country W Mitchell Banks, M D, F R C S, in his address as President of the Lancashire and Cheshire Branch of the British Medical Association, has discussed the subject of "Overcrowding in the Medical Profession and its Remedy " His remarks are so pertinent, and apply so well to conditions existing in this country, that I shall take the liberty of quoting at some length from his address

"Many circumstances have contributed to this overcrowding In former days a man of good family and social rank, but whose fortune was not very great while his children were numerous, could often find places for a son or two in the Church or in the Army, through the influence of powerful friends But the days of interest are gone, and these avenues are closed now As for the bar, the numbers of the briefless seem ever on the increase, while legal proceedings are actually diminishing in number In business, the quiet old trading days are done, and there is nothing but hurry and conflict and cheating and risk So that the merchant sees in medicine, a comfortable sphere of life, where a living can usually be made by any sober and industrious man Thus the great medical schools have been pouring out a deluge of young practitioners, which has overwhelmed the land"

After speaking of the demoralizing effects of the overcrowding of the profession, among those who are pushed to the wall on account of educational or social disadvantages, and of the ignoble methods often resorted to by graduates in medicine in order to keep the wolf from the door, Dr Banks proceeds to speak of the remedy for this condition of affairs, as follows

"The finest thing that has been done for the profession for many a long year was the enforcement of the five years' curriculum, and its effect in diminishing the numbers at some of the gigantic doctor factories has already been quite pronounced

"Well, then, you ask, what is my remedy? My remedy consists simply in stiffening up the entrance examinations I hold that there ought to be a rough sieve supplied at the very beginning, and that all who can not get through this sieve should be cast on one side As things stand at present, any man who gets through an entrance examination will ultimately get a qualification of some kind, which enables him to put "Doctor" on his door-plate, with just as much effect as a graduate in honors of the London University You can not hinder him from this by any amount of scientific or professional examinations He will rub through these, bit by bit y teacher of experience will tell you how futile it to attempt to turn back a man who has once ssed an entrance examination, if that man is dеermined to go on Beside, it seems to me unfair to allow an inferior man to enter upon a course of professional studies for which he is obviously unfitted He ought not to be allowed to get so far He should be turned back at the very commencement, and not encouraged to throw away years on unavailing work

"I have said that I consider the subjects of a medical education and the examinations therein to be amply sufficient if they are only properly kept up to the mark by due inspection But I do not admit this with regard to the entrance examinations These vary in the most remarkable manner, both as to subjects and the severity of examinations I have not been teaching students for nearly thirty years without knowing what I am talking about, and I say that there are in the profession at this moment, an enormous number of men whose general education is of the lowest type, and who never could have got into it if the entrance examinations had been of a proper standard Ask any examiner of experience what he thinks of the English of the papers he has to read, and he will tell you that it is often lamentable—spelling, punctuation and composition being simply set at naught

"Again, some six years ago, the Secretary of War sent a letter to the General Medical Council, complaining of the want of knowledge of their own language shown by candidates for places in the Army medical service I heard this letter read, and I never felt so ashamed of my profession in my life It seemed to me a most ignominious thing for us, that even soldiers should point the finger of scorn at us in the matters of general education"

Without doubt the remedy proposed by Dr Banks should be applied for the relief of a similar condition of affairs in our own country Uneducated men should not be admitted to our medical colleges as candidates for the degree of Doctor of Medicine The graduate who is deficient in knowledge of medicine may make good this deficiency before he is overburdened with practice, and if he has made no mistake in selecting his vocation will not fail to do so But the man whose early education has been neglected rarely overcomes this defect

As to the extent of the requirements at the examination for entering upon the study of medicine, I am not disposed to be as exacting as some would be A sound English education, such as may be obtained at the higher schools in our principal cities, and a sufficient knowledge of Latin for correct prescription writing, is all that we demand of candidates for the Medical Corps of the Army and, in my judgment, is all that should be required of the young man who desires to enter upon the study of medicine Certainly, this is not asking too much, in view of the fact that a considerable proportion of the recent graduates of medical colleges in this country are rejected by Army and Navy examining boards on account of their deficient knowledge of English grammar and orthography Steps have already been taken in some of the States to remedy this deplorable condition of affairs, by means of legislation regulating the entrance examinations In New York these examinations are now made under the direction of the Regents of the State University It is evidently a step in advance to make them independent of the colleges, and uniform as to standard

I must not dwell longer upon this topic, the importance of which no one will be inclined to deny, and will proceed to consider the reasons which have induced the Faculty of the Medical Department of Georgetown University to make a change in the hours devoted to instruction, and to extend the course of instruction to four terms of seven months each

In the Announcement for the present year the reasons for this change are stated as follows

"The demands of modern medical education are such that the faculty has found it necessary to extend the hours of instruction so that more time may be given to practical work in laboratories and hospitals"

Here we have a recognition of the fact that the graduate in medicine requires something which he can not get from medical books or lectures No doubt a bright man, by consuming the "midnight oil," might be able to pass a creditable examination at the end of a three years' course of evening lectures; but "the demands of modern medical education" call for something more than this, viz, for "practical work in laboratories and hospitals"

The student obtains his practical knowledge of anatomy in the dissecting room, and his skill and success as a surgeon depend largely upon the extent and precision of this practical knowledge This has long been recognized, and the candidate for graduation has been obliged to present evidence that he has done a certain amount of work in the dissecting room But it is only recently that our leading medical colleges have required a practical knowledge of chemistry, physiology, pathology and materia medica such as can only be obtained in the laboratory

The requirements for graduation of the Medical Department of the University of Georgetown are stated as follows

"The candidate must be of good moral character and at least 21 years of age He must have studied medicine not less than four years, during which he must have attended four full courses of instruction, delivered in some recognized medical school, the last of which shall have been delivered in this institution He must have attended at least two courses of practical anatomy, laboratory courses in physiology, chemistry, histology, pathology and bacteriology, and the clinical courses of instruction"

The laboratory work required is an essential part of a medical education, not only on account of the practical character of the knowledge acquired, but because of the special training in scientific methods and the development of a spirit of scientific investigation which results from such training

The great obstacle to the advancement of medical science in the past has been respect for authority and the acceptance of theories and supposed facts without submitting them to the test of experimental verification

/ The humoral pathology which Galen (born A D 130), developed from the previous teachings of Hippocrates, controlled medical thought and influenced medical practice for fifteen hundred years But we have been emancipated from the trammels of theory and superstition, and the medicine of to-day is largely based upon exact observation and experimental demonstration In other words, we may now properly speak of medical science—for, while our knowledge in many directions is far from being complete, it is founded upon a scientific basis of observation and experiment and is being rapidly extended by scientific methods

Scientific medicine, as taught in our medical colleges, includes all that is known of human anatomy and physiology, of pathology and clinical medicine, of the natural history of disease, and the influence of physical, moral and chemic agencies upon the human body in health and disease, of the action of drugs and their preparation for therapeutic purposes And the scientific physician is one who possesses a large share of this knowledge and has the faculty of applying it for the cure of his patients—without the natural aptitude and acquired skill necessary for applying his knowledge a man might be scientific, but could not properly be called a scientific *physician* His degree makes him a Doctor of Medicine, but not necessarily a physician, "A person skilled in physic or the art of healing" (Webster)

The scientific physician uses water of different degrees of temperature for the relief of various ailments, but he is not a hydropath, he makes use of electrical currents of different degrees of tension and potency for the treatment of such ailments as experience shows to be benefited by electrical treatment, but he is not an electropath, he uses alkalies to neutralize acids and cold baths to reduce febrile heat, but he is not an allopath, he rubs a frozen nose with snow and gives atropia in opium poisoning, but he is not a homeopath In short, he disclaims being any kind of a path[1] And in his name I protest against his being called an "old school" doctor If there is anything newer in medicine than the recent important additions to our knowledge of the causes of disease, and to the means of diagnosis and methods of treatment which have been made within the ranks of the profession during the past fifteen or twenty years I have not heard of it It is somewhat embarrassing for a recent graduate, who has been working hard for four years to acquire a knowledge of medicine in all its branches, to be asked by a well-meaning friend whether he is an old school doctor He should answer that he belongs to the new school of scientific medicine One of the leading features in this new school of medicine is the scientific spirit which asks in regard to everything, "Is it so?" and declines to accept an affirmative answer until an experimental demonstration of the fact has been made In the absence of such demonstration the scientific physician says "It may be so," "It does not appear probable," or "I don't know whether it is so or not" This unwillingness to assert that a thing is true in the absence of proof is a result of the kind of training which scientific men receive in laboratories, where everything is put to the test of experiment No doubt the physician who is thoroughly imbued with this scientific spirit is, to a certain extent, at a disadvantage when he begins to practice his profession To say "I don't know" requires considerable courage, especially on the part of a young doctor when the questioner expects to receive information and is willing to pay for it The unthinking and unscientific are very ready to believe that not knowing is due to ignorance on the part of the individual, when, in reality, it is the brief statement by a well-informed man that the matter referred to has not been determined and that no one can give the desired information Under the same circumstances an ignoramus or a charlatan, instead of confessing ignorance, would perhaps gain great credit by a positive assertion with reference to a matter of which he could not possibly know anything But science teaches that a confession of ignorance is the first step toward the attainment of knowledge When the anxious mother says "Doctor, is it diphtheria?" and receives the answer, "I don't know, there is a somewhat suspicious deposit upon the tonsils and I will at once make a microscopic examination and a culture which will enable me to determine the matter within twenty-four hours," she will probably not be as well satisfied with her medical attend-

---

[1] There have been several recent additions to the list of *paths* We have osteopaths biopaths and vitapaths etc In a western city in June last a coroner s investigation resulted in the finding that the death of a certain individual was due to the effects of drugs ignorantly administered by one Campbell who claimed to be a professor in a "Vitapathic" college In imposing sentence Judge Dustin said

"Men who knowingly go into a sick room and prevent anything being done for a dying man by silly incantations and laying on of hands are reponsible for his death and ought to be on a par with a murderer in the eyes of the law God help the dying man who relies upon you or any of the so-called graduates of this quackery You speak of vitapathy being of a higher power than medicine and you say you ordain *ministers* at the same time you matriculate vitapathic physicians Your methods are an insult to intelligence their practice is a criminal abuse of ignorance and your college a disgrace to civilization ant when she receives the assurance, after such an examination, that "it is not diphtheria," as she would have been with the non-scientific doctor who claims to recognize diphtheria at a glance, announces his diagnosis at once and "cures" the patient within a day or two The latter has earned the mother's lasting gratitude and she will not fail to recommend him to her friends as competent to cure any ailment to which humanity is liable But our scientific doctor will make his way in the end He will enjoy the confidence of his fellow-practitioners and his patients will learn after a time that when he says he knows a certain thing he really knows it, and when he says he don't know, he will do his best to find out, if the question can be solved by reference to the medical works in his library, or by an experimental investigation which it is practicable for him to make personally, or which can be made for him in a laboratory devoted to scientific research He does not make a snap judgment but waits until all the evidence is in It is evident that the opinion of a man of this type is of value His diagnosis, his prognosis and his advice as to treatment are based upon a careful investigation of the case in hand, a full knowledge of the literature relating to similar cases, and a precise appreciation of the indications to be met by the treatment prescribed

The conservatism which makes the scientific physician willing to confess ignorance is a very different conservatism from that of the pretentious charlatan and quack who gives an emphatic denial to facts that are well established, upon evidence with which he is not familiar or which his intellect is not capable of appreciating I have protested against calling the graduates of our leading medical colleges "old school doctors," but it must be admitted that there are still some very old school doctors among the former graduates of regular medical colleges In the ranks of the medical profession, as elsewhere, there are men who have been left behind in the rapid development of our knowledge, and who protest against the acceptance of facts which have been established by the most unimpeachable experimental evidence By such protest they simply reveal their own ignorance But as their opinions are often stated in good and forcible English, other persons, equally ignorant of the evidence, frequently accept them, or quote the old saying "When doctors disagree who shall decide "

As examples of this conservatism of ignorance, I submit the following quotations from two recently published papers, having the names of regular graduates in medicine attached to them In a report to a State medical society signed by a reputable physician, among other conclusions formulated, I find the following

"2 That the etiology of infectious diseases is as yet *sub judice*, and that therapeutic methods based upon the assumption that infectious diseases are caused by specific microorganisms are unscientific "

Another medical writer concludes a popular magazine article as follows

"We are brought, therefore, to this conclusion inevitably the germ theory is an assumption of causes, of the existence of which we have no evidence, to account for effects which they by no means explain "

The training which the medical student of the present day receives in the laboratory is essential for other reasons than because of the scientific spirit which is developed by personal verification of the facts which are recorded in his text-books of chemistry, histology, bacteriology, etc Not only does this personal verification impress the facts upon his memory, but he obtains that technical skill in the use of instruments and methods which can only be acquired by practice In the chemic laboratory he learns to detect poisons, to determine the nature of impurities in water or air, to examine urine, etc His practical course in histology makes him familiar with the use of the microscope and with the minute anatomy of healthy tissues In the pathologic laboratory he learns to recognize the results of different morbid processes and the presence of parasitic microorganisms in the blood or tissues, to distinguish between malignant and innocent growths, etc By cultivating the principal pathogenic bacteria, and examining them under the microscope after treatment with various staining agents, he becomes familiar with their biologic and morphologic characters and is able to recognize them wherever they may be encountered In short, he obtains a practical knowledge of many things which it is essential for him to know, in order that he may be a skillful physician The knowledge to be obtained from books, which enables the student to pass a creditable examination, does not make him a chemist, a pathologist, a skilful diagnostician, a surgeon or a physician, any more than the knowledge to be obtained by reading books on agriculture makes a man a farmer, or than the study of books on navigation would enable a man without practical experience to take command of a trans-Atlantic steamer It is in recognition of this fact that the Medical Faculty of the University of Georgetown has, as already stated, decided to extend the hours of instruction "so that more time may be given to practical work in laboratories and hospitals " Every physician of experience will approve of this decision It is true, that but few of the prominent physicians of the present day enjoyed such advantages as it is proposed to give to their successors It is also true, that a majority of these prominent physicians were very imperfectly prepared for the duties and responsibilities of a general practitioner when they received their medical degree This fact has long been recognized within the ranks of the profession, and it is for this reason that hospital appointments have been so eagerly sought by those having a proper professional ambition In the hospital, the young doctor learns to apply his knowledge and to meet emergencies with composure and professional skill His books have taught him what to look for, what to listen for and what to feel for, but practice alone can give him the trained eye, the trained ear and the *tactus eruditus* of the accomplished physician

In the "Circular of Information" already referred to, I find the following announcement

"A laboratory course in bacteriology will be given, which will continue over one half of the session This will consist of bacteriologic technique, and the study and diagnosis of diseases which are caused by microorganisms

"The student will also be given opportunities to observe and investigate special problems in clinical diagnosis, disinfection, etc

"The laboratory course is obligatory "

I am especially pleased with the last clause of the quotation just read "The laboratory course is obligatory " And I trust that this applies to all of the laboratory courses For I am convinced that these constitute an essential part of the practical training of the scientific physician. It is in the laboratory that the student acquires deftness in delicate manipulations required in his chemic, histologic and bacteriologic studies; here he learns to measure with accuracy, to appreciate the slight differences in color reaction, in form or in structure, upon which he must often depend for the recognition of toxic agents, pathogenic germs or abnormal growths; his eye becomes trained to recognize the malarial plasmodium, the tubercle bacillus and other microorganisms which are only revealed to us by the highest powers of the microscope, under proper illumination, and in skillfully mounted preparations; and it is here that conditions are most favorable for the development of that spirit of doubt and inquiry which is so essential for the progress of scientific medicine. Where there is no doubt, there will be no investigation. The farmer who accepts the traditional belief that certain seed must be planted in the light of the moon, in order to obtain the best results would consider it a waste of time to make a comparative experiment. But it is by means of comparative experiments that we arrive at definite conclusions in the laboratory, and the great diversity of opinions with reference to the curative action of drugs is largely due to a failure to apply the same methods in practice. This failure has been partly due to want of appreciation of the necessity for a control experiment in judging of the results supposed to follow a certain course of treatment, and partly to the difficulty of making such a control experiment in clinical medicine. The unscientific mind jumps at conclusions that are entirely unjustified by the facts. The warts upon the child's hand are rubbed with a piece of meat which is thrown over the left shoulder, etc., and they subsequently disappear; a horse chestnut or a potato is carried in the pocket for years and the individual does not suffer from rheumatism during the entire time. The child has a high fever at bed time, the mother gives it a sugar pill and the next morning the fever has entirely disappeared, and so on, *ad infinitum. Post hoc ergo propter hoc.* But the man of science asks, What would have happened if the warts had not been rubbed with meat, or saliva, or whatever may have been the particular fetich employed? Would the man have had rheumatism if he had left the horse chestnut on the tree or the potato in the ground? Would the child's fever have disappeared if the mother had failed to give it the sugar pill? To determine this, a comparative experiment is evidently required. Take the case of the child, for example. To determine whether the disappearance of the fever was in fact due to the administration of the sugar pill, we should have another exactly similar case—a child of the same age, under similar conditions and suffering from an elevation of temperature due to the same cause. One child should have the pill and the other should have nothing. Even then, the result would not be conclusive. Science demands that the experiment should be repeated several times. There are so many chances that the conditions may not, after all, have been exactly identical. No truly scientific man would venture to announce a fact as established upon the basis of a single successful experiment. And, having in view the fallibility of human judgment, the tendency to draw conclusions favorable to the prejudices or desires of the individual, and the frequency with which erroneous conclusions are published upon what appears to be a substantial experimental basis, science demands verification of reported results by two or more independent investigators before finally accepting these results as demonstrated facts. All this is so far away from the ordinary methods of arriving at conclusions that the conservatism of the scientific physician meets with little sympathy on the part of the general public. The man with a horse chestnut in his pocket is not only convinced by his individual experience that this is a sovereign cure for rheumatism, but he is apt to resent your non acceptance of his experiment as conclusive. We, on the other hand, know that medical literature abounds in instances of the ultimate failure of therapeutic agents and methods of treatment which have for a time been lauded as specific and have been indorsed by prominent physicians. We are therefore becoming more and more exacting in our demands as regards proof, and, as a result, medical science is making rapid progress. How great this progress has been is not fully appreciated by the nonmedical public.

While we justly pride ourselves upon the rapid development of our knowledge during the last half of the present century we must not forget that, in some directions, the foundations of scientific medicine were substantially laid by the illustrious physicians of the past. The time at my disposal will not permit me to give an extended review of the development of medical knowledge, but a brief reference to some of the more important events which have marked this progress will perhaps be useful, as showing the extent of the field and the advantages which the physician of to day has over his predecessors.

Hippocrates and his illustrious successors Celsus, Galen and others, were certainly the peers of modern physicians in their powers of observation, and we are indebted to them for a mass of recorded facts relating to disease which have been verified and added to by subsequent observers. But observation, in the absence of the instruments and methods of modern science, goes but a short distance in the direction of unveiling truth, and often leads to erroneous conclusions. Observation led the ancient philosophers to believe that the sun goes around the earth and that water and air are elements. The experimental methods of modern science have revealed to us the constant presence of three elementary gases in the atmosphere, one of which is also a constituent of water, while one—argon—has only just been revealed to us by the researches of Professor Ramsey and Lord Rayleigh. One of the first lessons to be learned by the student of medicine is not to trust implicitly to the evidence of his senses. This is the fundamental error of ignorant persons and the foundation of demonology, and superstitions of all kinds. The eye tells us that water from the well is perfectly pure, but the microscope shows us that it swarms with living organisms. The touch tells us that the patient has a high fever, but the clinical thermometer says, no—the sensation received was due to the comparatively low temperature of our own hand at the time of making the observation, etc., etc.

The anatomic knowledge of "the father of medicine" was very imperfect, because it was not obtained by the dissection of the human body. The Greek physicians Herophilus and Erasistratus, of the Alexandrian school of medicine, who lived about 300 B. C., are believed to have been the first to study anatomy in this way, and from that time our knowledge in this essential department of medicine has steadily increased until, at present, it is perhaps more nearly complete than in any other branch. The medical student of to day is expected not only to acquire an accurate knowledge of anatomy in the dissecting room, but he must study the minute anatomy of the tissues by means of the microscope and the methods of investigation which he will learn in the histologic laboratory. He is also expected to have at least an outline knowledge of comparative anatomy, a branch of scientific research which dates back to the time of Aristotle (384 B. C.), and which has been greatly developed during the present century. Our knowledge of minute anatomy has been largely acquired during the past sixty years, as a result of the improvements in the compound microscope made about 1830. The perfecting of this invaluable instrument of research has also led to vast additions to our knowledge in the department of general biology, of which it is important that the medical student should possess at least an outline. A knowledge of the structure and development of lower organisms is justly regarded as a proper introduction to the study of human anatomy and physiology. Embryology, a branch of science which may almost be said to have had its birth in the present century, must not be neglected by the student of medicine. It is true that Galen made observations upon the development of the incubated egg, and that Harvey, in the seventeenth century, made some important observations in the same line of investigation, but the minute and accurate knowledge of the present day depends upon the comparatively recent improvements in the compound microscope just referred to.

Progress in physiology, as in other branches of medical science, has resulted from the application of the experimental method to the problems to be solved. Galen made an important addition to human knowledge when he demonstrated that urine is secreted by the kidneys, a fact which, apparent as it seems to us to be, had not previously been recognized. It was nearly fifteen hundred years later that Harvey (1628) demonstrated the circulation of the blood, a discovery which is justly considered one of the most notable events in the history of medicine. The subsequent explanation of the process of respiration by Lavoisier (1783), the experiments upon gastric digestion by Beaumont (1834), and the discovery of the function of the vasomotor nervous system by Claude Bernard, opened the way to a fertile field of research which is still being vigorously prosecuted in physiologic laboratories, and the results attained constitute an essential part of a medical education. The progress of our knowledge of physiology has necessarily been secondary to the advancement of chemistry. Indeed, physics and chemistry constitute the foundation of medical science. We therefore place Priestley's discovery of oxygen (1783) among the epoch-making events in the history of medicine. It is due to chemistry that we are able to use the active principles of various drugs of demonstrated value, instead of the crude material—leaf, root, or bark, and the chemists have recently made many valuable additions to the list of approved therapeutic agents—principally from the series of coal-tar products.

The importance of carefully studying the results of morbid processes in the post mortem room and in the pathologic laboratory is now generally recognized, and the medical student will find that since Morgagni (1682 1771) led the way in the study of morbid anatomy, an enormous amount of work has been done in this field of investigation. He will be required to make himself familiar not only with the facts developed, but with the methods of research and the microscopic and gross appearances of tissues which have undergone the changes due to disease. Important as these studies are, the results obtained, from a practical point of view, are eclipsed by the brilliant discoveries which have been made during the past twenty years with reference to the etiology of infectious diseases which to a considerable extent have been prosecuted in laboratories devoted to pathologic research. These discoveries, like others heretofore referred to, depend primarily upon the improvements which have been made in the compound microscope, especially in high power objectives and means of illumination, and upon methods of research devised by the pioneers in this field of investigation, among whom the names of the French chemist Pasteur, and the German physician Koch are preeminent.

The development of our knowledge relating to the bacteria dates from the controversy relating to spontaneous generation, which was finally settled by the experimental demonstration made by Pasteur (1860), that no development of microorganisms occur in organic infusions which have been sterilized by boiling, and that fermentation and putrefaction depend upon the introduction of living germs into such infusions. The distinguished French physician Davaine, first demonstrated the etiologic relation of a microorganism of this class to a specific infectious disease. The anthrax bacillus had been seen in the blood of animals dying from this disease by Pollender in 1849 and by Davaine himself in 1851, but it was not until 1863 that the last named observer felt himself justified in asserting, as a result of inoculation experiments, that the bacillus was the essential etiologic factor in the production of anthrax.

In 1873 the German physician Obermeyer, discovered the spirillum of relapsing fever in the blood of patients suffering from that disease. The typhoid bacillus was discovered by Eberth and independently by Koch in 1880. The same year the present speaker discovered the pathogenic micrococcus which is now recognized as the cause of croupous pneumonia. In 1882 Koch published his discovery of the tubercle bacillus. The glanders bacillus was discovered by Loffler and Schutz in 1882, the bacillus of diphtheria by Loffler in 1884, the bacillus of tetanus by Nicolaier in the same year. It was also in this eventful year that Koch published the discovery of the cholera spirillum. Since these important discoveries our knowledge of the pathogenic bacteria has rapidly increased, and it is now demonstrated that erysipelas, septicemia, puerperal fever, wound infections, boils and abscesses, peritonitis, pleurisy, etc., are due to general or local infection with germs of this class.

Evidently the medical student of the present day must be made familiar with these recent additions to our knowledge of disease, and his acquaintance with these microscopic foes of the human race should be of that practical character which can only be obtained in the laboratory.

I have already occupied so much time that I can refer but briefly to the advancement in clinical medicine, which depends largely upon additions to our knowledge already referred to The use of the stethoscope, the clinical thermometer, the laryngoscope, the ophthalmoscope and other aids to diagnosis has introduced certainty in place of uncertainty, science in place of guesswork Our knowledge of the pathogenic bacteria tells us not only where to find them, but how to destroy them when they are accessible to the action of physical or chemical agents This knowledge has undoubtedly resulted in the saving of thousands of valuable lives This has been accomplished by means of antiseptic or aseptic methods in surgical and obstetrical practice and by the intelligent use of disinfectants for the destruction of infectious material wherever it may be found As a result of such procedures we have during recent years escaped any devastating epidemic of cholera or yellow fever, although the first mentioned disease has twice been introduced into the harbor of our principal seaport, and yellow fever prevails annually in the cities of Havana and Vera Cruz, with which we have close commercial relations

The medical student is expected to prepare himself for continuing the work of his predecessors in preventive medicine, although this work has a constant tendency to diminish the demand for his services To the credit of our profession be it said that this selfish point of view has never controlled its action, and it is largely to the efforts of physicians that existing laws and regulations have been enacted for the prevention of the extension of infectious diseases, the maintenance of a pure water supply for towns and cities, and the general sanitary supervision exercised by local and State boards of health

The most notable additions to our therapeutic resources are the antitoxins of diphtheria and tetanus, and the use of thyroid extract for the cure of myxedema But I can not dwell upon the possibilities in the way of specific medication which are suggested by these recent achievements of scientific medicine Certainly I have said enough to indicate to the young man who contemplates entering upon the study of medicine that his best energies will be needed to master all the important details in the various branches to which reference has been made, and to justify the Medical Faculty of the University of Georgetown in extending the hours for instruction and in requiring that students shall take the practical laboratory courses which have been arranged for, as announced in the recent Circular of Information already referred to

Having attempted to give you some idea of the present status of scientific medicine, I desire briefly to call your attention to certain matters which are extremely discouraging for the truly scientific physician although he seldom refers to them, and, perhaps wisely, trusts to time and the diffusion of knowledge to remedy the evils to which I shall refer

Hand in hand with the progress of medical science we see an army of pseudo scientific quacks who trade upon the imperfect knowledge of the masses, and by plausibly written advertisements convince many, even of the educated classes, that their particular method of treatment is based upon the latest scientific discoveries A Priestley discovers oxygen, the physiologists show that this gas is essential to life and that the maintenance of a full degree of vital activity depends upon the possession of healthy lungs of ample capacity and the respiration of pure air, the scientific physician discovers defects in the respiratory apparatus, and under certain circumstances prescribes oxygen for the relief of symptoms resulting from a deficient supply of this life sustaining gas But the pseudo scientist extols oxygen as a cure all for pulmonary complaints, or invents an apparatus which may be held in the hand or carried in the pocket by which oxygen will be absorbed in some mysterious way, and without difficulty obtains numerous certificates as to the marvelous cures effected by his method A Franklin draws lightning from the clouds, a Galvani shows that an electrical current may be developed by the contact of metals and that such a current causes muscular contraction, and innumerable patient investigators add to our knowledge of electricity The scientific physician avails himself of this potent agent for the treatment of certain ailments in which it appears to be indicated, but admits that he meets with many disappointments in his clinical experiments The pseudo-scientific quack writes, or has written, advertisements in which fact and fiction are so commingled that even educated persons may be deceived, and having aroused interest in the alleged therapeutic value of this mysterious agent, offers his electric belt, or finger-ring made of two metals, or pocket battery as a sure cure for certain specified ailments, or, if less modest and more certain of the credulity of the public, as a cure for all of the diseases to which man is subject

Again, a Pasteur proves that the disease of sheep and cattle known as anthrax is due to a microscopic organism found in the blood, an Obermeyer discovers a different microorganism in the blood of relapsing fever patients, and numerous patient workers in laboratories rapidly add to our knowledge of pathogenic bacteria Then comes the man with the microbe killer He tells you that all diseases are due to germs in the blood and that his fluid kills them without fail Science has demonstrated that comparatively few of the infectious diseases of man are due to the presence of pathogenic bacteria in the blood, and that the microbe killer has but very little germicidal value, but a credulous public accepts the interested statements which appear to have a scientific basis, and swallows the microbe killer with impunity if not with benefit And so it goes Science establishes the value of the thyroid extract for the cure of myxedema, and immediately the public are called upon to swallow extracts of brain for cerebral trouble, of heart for cardiac disease, etc Even the Chinese pulse doctors obtain a large clientèle on the Pacific coast Their solemn looks and pretentious claims impose upon the ignorant and it is said that even educated people not infrequently consult them It is true that in China, as elsewhere, there are two classes of physicians Those who are educated and who are familiar with the medical classics of their country, and the itinerant quacks who are not only ignorant but unprincipled No doubt the regular practitioner in China believes in his own pseudo-science According to a recent author [1] "The learned Chinese doctor is not ignorant in the sense that he has not studied, as from early youth he has been subjected to a degree of cramming and of learning by rote, such as would discourage and wear out the less patient and less toiling Caucasian He has been obliged to learn stacks of sacred precepts taken from their most ancient sages, and the admixture of intricate and bewildering astronomy, meteorologic signs, and the endless physical complication of concurrent signs, appearances and detached disturbances that he has been compelled to learn by heart is simply appalling Anatomy and physiology cut no figure in these studies and they are considered unnecessary, as disease is a matter depending on good or bad vapors, and is of either divine or diabolical origin In spite of their most elaborate treatises upon the pulse, from which they profess to be able to perform the most skillful diagnoses, they are even unacquainted with the existence of the circulation "

---

[1] Dr P C Remondino of San Diego, Cal

The time at my disposal will only admit of a brief reference to the Chinese theories relating to disease and its treatment As was the custom among the more enlightened occidental nations, until a comparatively recent period, their prescriptions often contain twenty or more ingredients, apparently given with a vague idea that one out of the number may prove to be the right remedy These ingredients are obtained from all imaginable sources and include all kinds of nastiness, in the way of excretions, desiccated animal tissues, etc With them, the color of a medicine is an essential character, red medicines being suitable for diseases of the heart, white for pulmonary complaints, black for diseases of the kidneys, green for those of the liver, and yellow for those of the stomach In the use of remedies from the vegetable kingdom, the leaves and branches are most appropriate for diseases of the extremities, the bark should be used for skin diseases, the pith for derangements of internal parts of the body, etc

In conclusion, I desire to emphasize the fact that learning does not enable a man to distinguish between science and pseudo science The learned disciples of Confucius in the Orient, and classical scholars of the pre-scientific epoch in occidental countries, failed to distinguish between the facts of astronomy and the fancies of astrology And, at the present day, eminence as a classical scholar, or as a theologian, or as a jurist, or as a metaphysician, in the absence of a knowledge of the methods and results of modern scientific investigation, does not enable a man to distinguish between science and pseudo-science in medical practice This kind of learning is therefore not essential for the physician, but, as we insisted at the outset, he should not enter upon the study of medicine without having, at least, a thorough knowledge of his own language and of those branches of study pursued in the high schools of our large cities, we now add that a reading knowledge of the French and German will be very desirable if he wishes to keep entirely *au courant* with the progress of medical science

---

The Angels of the Ambulance —Mrs Margaret Sangster has contributed to *Harper's Weekly* the following stanzas concerning the young medical "angels" of our cities ambulances

"I never see in our bustling town,
Where the midsummer sun pours fiercely down,
The swift onrush of the ambulance
But I think of the blessed countenance
Of One who walked by lane and field,
And with voice and look the suffering healed
Still, where the city's woes are thick,
The dear Christ spirit heals the sick
And yet He lives in the hearts of men,
And sends His angels with speed again
Wherever the weary plod and fall,
His care and tenderness over all

"And the angels carry lint and lance
And drive in the city's ambulance
Are bluff of speech and deft of hand
And quick with accents of command
And the wind of their coming clears the way
For a breath of heaven in the darkest day"

WHAT THE PATIENT EXPECTS, AND WHAT WE ARE ABLE TO DO, IN CHRONIC CATARRH OF THE TYMPANUM OR MIDDLE EAR, WITH DEAFNESS

Read in the Section on Laryngology and Otology, at the *Forty sixth* Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10, 1895

BY LAURENCE TURNBULL, M D, PH G

Aural Surgeon to the Jefferson Medical College Hospital, President of the Sub Section of Otology of the British Medical Association, and the Section on Laryngology and Otology of the AMERICAN MEDICAL ASSOCIATION *Emeritus Physician to the Department of Otology* of the Howard Hospital Member and one of the Committee of the International Congress of Otology

PHILADELPHIA

In the treatment of all chronic diseases of from six months' to as many years' duration, the prognosis, or what we are able to do, depends upon many factors The first, as a rule, is the duration, the second is if the case is functional, the third, if organic, it is incurable This not only applies to the ears but to the lungs, liver, kidneys, eyes and brain

Can we improve them? We can, if the disease is functional and not organic When the patient with organic disease of the lungs applies, not for a cure, but for relief, we frequently are able to diminish the cough and expectoration, build up the general health, and by changing the habits and climate, improve the case So also with the liver, kidneys and brain In the case of the eye, sometimes by a skillful and delicate treatment or an operation we are able to give one-sixth, one-eighth, one fourth or even one-half the amount of vision, by which, with the assistance of glasses properly fitted, the patient is able to make his way alone, and even to read and work This slight improvement is almost always accepted with cheerfulness and even gratitude The most unreasonable of all patients to be treated, both in public and private, are the deaf They come to the aural surgeon and expect a *cure*, not relief—and the general public and the quack encourage them in this demand Many of them come with varying deafness, from *nil*, to hearing the ordinary watch close to the ear, and when by prolonged treatment, they are able to hear from ten to twelve inches, or more, also one person's conversation, or, by the aid of the trumpet, ordinary conversation, they are never thankful, but state that So-and-So was cured of deafness, not knowing that in our list of diseases of the ear causing deafness there are hundreds of cases from cerumen or ear wax, resting on the drum membrane, or a slight catarrh in the nose, throat or Eustachian tube, to disease involving the internal ear, auditory nerve or brain There are also a number of inherited diseases of the ear and those contracted by impure habits, which cause most profound deafness never to be cured when of long duration Then there is accompanying these forms of deafness, constant and persistent noises termed tinnitus aurium, or ringing sound, which as a rule is absolutely incurable after months of careful treatment This tormenting, distressing condition which is only a symptom of a deeper form of the diseased ear, causes great unhappiness in the individual This class of patients is of a very jealous disposition, ready to quarrel even with their best friends, they also imagine without cause that persons are talking about them, stating something wrong because they do not hear With the assistance of certain medicines, and true desire on their part, these sounds may be ameliorated, and if the patient is willing to aid the physician, not permitting the mind to dwell upon them, great comfort may be received If, instead of this effort on their own behalf, and a willingness to follow the counsel of their friends and aural surgeon, they become morbid and irritable, keeping by themselves, avoiding all pleasant company and amusements which could be had by the aid of the hearing trumpet, or still better, hearing with their eyes, these noises will sometimes become unbearable and a form of insanity ensues, and in some very rare cases in an insane moment of desperation they commit suicide That is the reason why they should avoid the causes which increase it This is no fancy sketch, but sober truth No wonder the aural surgeon is pleased to be able by various operations to endeavor to relieve them from this dreadful form of disease, as well as aural vertigo, in which the patient is liable to fall forward, or sometimes backward at the risk of life

ILLUSTRATIVE CASES

These cases will be selected mostly from our own observations, and one from our colleague, Dr MacCuen Smith, the histories being brought up to the month of May, 1895

Case 1—M K, a lady of refinement and education, aged 40, *having met with* reverses had to resort to a manufacturing establishment for a living She suffered for years with chronic aural catarrh (dry) never having had any discharge, with chronic rhinitis and progressive deafness, which entirely unfitted her for performing her duties In spite of the usual treatment for years, she was so deaf that she was desirous of an operation, hoping thereby to obtain relief She was taken to Jefferson Medical College Hospital Feb 6, 1891 For twenty-four hours she was placed under very limited diet, with gentle purgatives and kept at rest in bed On the morning of the operation she had a very light breakfast (The urine had been tested for albumin and a careful examination made of the heart both of which were found in normal condition) The chief surgical resident administered the anesthetic, ether, of which she took a considerable quantity without going under its influence Finding this to be the case, chloroform was administered with care and the ether withdrawn This agent acted very promptly but on examination of her pulse it had ceased to beat The chlo form was withdrawn and efforts were made at resuscitation with artificial respiration, with depression of the head and elevation of the lower extremities, after a time the pulse returned and the operation of removal of the ossicles was successfully performed She had some vomiting which was not excessive as she had taken internally a few doses of solution of cocain, and sulphate of strychnin The parts were cleaned with iodoform cotton, and the ear carefully packed and not disturbed for twenty four hours then the cotton was replaced The ear was covered with a large mass of absorbent cotton, and a bandage applied No food was given until the stomach was quiet, and all noises were avoided, as even walking across the room was painful to her

The blood was carefully mopped up, and soon the ear became dry No wash of any kind was used and in the course of one week she was allowed to sit up and permitted to go home, though she continued coming to the writer's office to have the ear dressed The membrane which had been removed was soon restored by pseudo membrane and was prevented from adhering to the promontory by keeping the Eustachian tube free, by the use of Politzer's douche, and the vapor of ether

The restoration of her hearing was most successful for general conversation at about five feet She was able to resume her daily duties, putting up medical preparations, and to receiving orders even in a moderately loud voice, and heard an 18–36 inch watch about half the normal distance It is now three years since the operation and the patient has been exposed to all sorts of weather having to travel at least a mile to her work at the establishment through one of the coldest winters of many seasons She only came a few times to the office to have removed some slight accumulations of a light color, and to have her nose and pharynx cleansed with antiseptic sprays and the Eustachian tube kept open

Case 2—*Operation for the Relief of Deafness and Vertigo*—M H F, aged 45, a lady of wealth and refinement, had been deaf ever since she was very young, and she stated this was the result of scarification of the tympanic membrane by the physician who first had her case in charge She had suffered with a diseased throat, with a deviation of the septum very high, and enlarged glands She takes cold easily and suddenly the swelling of the throat and nose being very great, followed by intense deafness She had been under the treatment of several laryngologists, electricians and aurists, but only with temporary benefit

*On examination there was found in the right ear, thicken*ing of the membrana tympani, the handle attached to the promontory, and the whole malleus twisted on its axis, Eustachian tubes patulous, H D watch pressed on contact Tuning fork full C, auditory nerve normal bone conduction good Excessive tinnitus and vertigo The left ear was in similar condition The operation was performed, chloroform and ether being used, Feb 5, 1892 The malleo incudal joint was firmly ankylosed The membrana tympani, the malleus and the incus were removed The operation was attended with some difficulty on account of the hemorrhage Hearing was improved after the operation, and the tinnitus had decreased

June, 1893, hearing continued, a new membrane had formed and the hearing in that ear had become defective after a time The membrane was incised but the hearing was not what was desired, and a few months later the other ear was operated upon, when she was able to hear ordinary conversation, to give orders, and to attend to shopping and all outdoor work She could then hear her own watch four inches off, and even a clock in the opposite room

One of the most distressing symptoms which this patient suffered from, was intense vertigo so that she would fall back without notice, and she was afraid all the time that this would happen on the stairs The operation relieved the vertigo, but did not entirely the roaring tinnitus, which was caused in part from mucus in the orifice of the Eustachian tubes and from the diseased nose, in spite of careful treatment

In a note received October, 1894, two years and a half after the operation, she wrote "I can get about *very well in the stores* I have not the least trouble and always understand what is said, for those who are not deaf raise the voice on account of the street noises so that I have little difficulty to understand all that is said, but when it is quiet, there is my trouble "

Even when writing this, she was suffering from an acute nose and throat catarrh, for she adds "I wish I had some of those benzoate of soda tablets which I took before, when my breath, nose and throat were out of order, they acted well with my stomach " (The same catarrhal condition)

The great improvement which followed the operation on the left ear she stated continued, but the right side filled up at times so as to require the application to the nose and throat of a spray and exhauster, and even the galvanic current, which for the time caused a slight return of the dizziness, but which soon passed away with improvement of hearing

This patient stated in another note, that her hearing always improved when she could breathe salt air, and that the tinnitus and deafness were brought on by constant worry This the doctor can not always prevent, but can aid in change, and removal of the cause We feel, as physicians, we can do much to ameliorate the condition of the nervous system In another place she writes "Your patient still *hopes for a better time coming,*" and again, "Your patient is not of an unhappy disposition, but under ordinary circumstances would be bright and happy "

These peculiar physiologic and psychologic matters have, as aural surgeons and physicians know, much to do with both deafness and the peculiar noises which are heard by certain classes of nervous or neurotic patients and we must be physicians of the mind as well as of the body

Case 3 —A Case of great Relief to Tinnitus Aurium —H M , aged 24, a student of medicine, has been a sufferer with chronic middle ear catarrh and tinnitus aurium with, first, acute and subsequent chronic rhinitis He was in the office and studied with a distinguished throat and ear specialist, and was treated with great care, still his suffering was so great that it interfered with his studies His nervous system was very impressionable to all kinds of drugs, and he had employed every means of relief, even to the freezing by ether and rhigolene over the mastoid, etc He made up his mind to have an operation performed He was not willing to go to bed, but was operated on in a laryngological chair at the Jefferson Medical College Hospital, August, 1893 The local anesthetic was a 10 per cent ointment of cocain which had been applied to the drum membrane the night before, and early morning of the operation The malleus was removed with a portion of the membrane, so that access was had to the incus and stapes Mobilization was then employed, and after a few days when the parts were healed he experienced considerable relief from the noises He did not desire any other operation as his hearing was not very defective on that side

DR MACCUEN SMITH'S CASE OF OPERATION FOR DEAFNESS, PAIN AND VERTIGO

Mrs H G , aged 42 years, N J , twelve years ago was treated for severe tinnitus in both ears for a continuous period of two years, which, however, failed to be improved', at times the noises were more intense At the expiration of these two years, the hearing (which had been gradually growing dull) suddenly became much worse Accompanying this unexpected impairment of hearing was an attack of vertigo that has continued at intervals ever since, about seven years The hearing power in this time has become greatly impaired For the past four years she has suffered periodic pain in the right ear, sometimes being very acute, and it would last for one or two days It is needless to say that this patient consulted various authorities, but no permanent benefit was derived In June, 1892, when she consulted us, the membrana tympani was found, R E , chronically inflamed and firmly adherent to the promontory, could hear only loud conversation at fourteen inches , watch and fork were audible only on contact , bone conduction was normal Has never had any discharge On account of the increasing tinnitus, vertigo and pain, the patient refused any line of treatment except operative, and we could see no good reason why we should extend any hope for relief by following in a line of non-operative treatment that had failed in the hands of several competent physicians

June 6 we excised the membrana tympani, malleus and incus, and packed the cavity with iodoform gauze In three days this packing was renewed, at which time the pain was entirely relieved, the hearing was improved somewhat, although the vertigo continued Two weeks after the operation the hearing was markedly benefited, the pain did not return, and the vertigo somewhat improved In this condition she left the hospital, and I did not see her again for three months Reports her health very good, hearing about two-thirds normal, pain and vertigo both relieved Have seen the patient at intervals for two and a half years after the operation, and the above improved condition has continued uninterruptedly

These three cases, with the one by Dr Smith, which could have been increased by many others, cover the good results of the operations in *pain, deafness, vertigo and tinnitus aurium*

255 South 17th Street

The *Lancet-Clinic*, of Cincinnati, calls on the Ohio doctors to defeat at the next election all of those candidates for reelection to the Legislature who refuse to vote for a medical bill, and those who voted against it We agree with our contemporary that it is quite time medical men understood everywhere the value of organization and the necessity for standing solidly together in those matters in which they have a common interest The reason why the politicians have paid little attention to the profession is because the profession have paid no attention to the politicians A sound thrashing occasionally would secure wholesome respect

---

WHAT ARE THE CURATIVE EFFECTS OF PNEUMO- AND PHONO-MASSAGE ON THE MIDDLE AND INTERNAL EAR?

Read in the Section on Laryngology and Otology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7-10, 1895

BY LOUIS J LAUTENBACH, M D , Ph D

PHILADELPHIA

This paper which I have the pleasure of presenting to you, is but an effort to explain the results achieved by my method of employing ear massage I first presented the subject of ear massage to the Pennsylvania Medical Society in May, 1894, and in two subsequent communications to the Philadelphia Medical Society, one in May, the other in September of the same year, still further outlined the method and its results

Recalling for a moment the method and its use, you will remember that I employ it always through the external meatus by means of double or single ear tubes fitting tightly in the canal, and that I use either pneumo phono or mixed massage By pneumo-massage I mean the massage occasioned by the impact of a column of air thrown inwardly on the drum-head, or, where this is perforated or not present, into the middle ear, or else by the suction effect of a partial vacuum being created within the ear tubes—these air movements being unaccompanied by sound Phono-massage refers to the carrying of sound of various pitches and volumes through the meatus to the drum-head and middle ear By mixed massage, I refer to the carrying of the two kinds, phono and pneumo at the same time Practically, pneumo-massage is always, to a greater or less extent, accompanied by some phono-massage, from the fact that the mechanical appliances producing it are always more or less noisy My experience with these methods has been extensive and on the whole successful Their relative value in each individual case is as yet not perfectly clear to me, but each it will be found has its special sphere of usefulness

When we consider how difficult and inaccessible to treatment is the ear, we can but acknowledge that forms of treatment so easily applied as these, if found to exert any influence on this organ, must prove exceedingly valuable

We will first consider the influence of pneumo-massage on the various ear structures, premising our remarks with the assertion that to a degree the phono-massage has a like effect, in addition to a direct action which it exerts on the ear nerves By the application of pneumo-massage by my vacuum method, we occasion an outward motion of the drum-head, with a swing of the handle of the malleus and an outward movement of the entire chain of ossicles with a withdrawal of the stirrup from its close application to the oval window By reason of this withdrawal, there is occasioned a movement of the labyrinthine fluids, in addition to this, the attenuation of the air of the middle ear exerts an outward drawing effect on the membrane of the round window, which in turn causes a disturbance of the labyrinthine fluids immediately within it By this motion of the fluids the otoliths are thrown into action and excessive pressure within the semicircular canals and cochlea is temporarily overcome In consequence of this, the pressure on the nerves is relieved and they are given time to recuperate, at the same time the circulation is stimulated, and because of this general activity, effete products are removed and morbid changes controlled The middle ear and all its various structures including the Eustachian tube are affected by the massage and participate in the renewal of these active circulatory changes

Phono massage occasions all the changes above mentioned, but in a minor degree only However, in addition, it affects the ear nerve's function by sending a repeated or a continuous message over it—this latter method of using a continuous sound to stimulate a diseased ear nerve, I now rarely employ The phono-massage resembles pneumo massage in causing a to and-fro movement of the ear conducting apparatus, but the number of movements per minute is very great, depending upon the pitch of the sound, and the amplitude of motion is exceedingly small as compared with that produced by pneumo-massage While this form affects the middle and internal ears, it affects also the auditory nerve, and if the sounds be not too long continued the effect on the nerve is apt to be good and a stimulation is produced, but if long continued or following too quickly, one wave upon another as in the use of high notes, or when too loud, the effect is apt to be harmful by exhausting the nerve substance or by tiring the nerve's central ganglion The method which I most frequently employ—a combination of mild and regular pneumo massage with mild phono massage—affects the structures as above mentioned, and has, in my hands, proved the most advantageous Under its influence you can observe the drum-head bulge outwardly, its circulation increase, and the hearing faculties improve, while often headaches and full, heavy and giddy feelings caused by pressure upon the labyrinth or from morbid ossicular adhesion or constriction of the blood vessels disappear At the same time, the ear nerves begin to regain their full functional activity and there is a marked improvement in the hearing as tested by bone as well as by aerial conduction

The results obtained by these methods on the internal ear have far exceeded my anticipations Having been taught the hopelessness of the treatment of diseases of the internal ear, it has been a subject of great surprise and pleasure to find that by such methods even cases of extreme disease of this structure could be improved I have now quite a number of patients who belong to the class ordinarily known as that of the deaf and dumb, where, by the most accurate and careful ear testing of which I have any *knowledge—the phonographic* method—not the slightest positive evidence could be obtained of the faintest trace of hearing One of these cases, a boy aged sixteen months, after his third treatment could hear the sound made by turning the knob of the door, not seeing it opened Another, a girl of 4 years, in whom I could not demonstrate the least vestige of hearing, has developed not only the power of hearing certain sounds, such as the creak of a spigot, the bark of a dog, the noise of a door knob's motion, but has in addition developed the power of imitating some sounds When her father, in playing the violin, strikes the A string, she invariably imitates it, even when the instrument is not in sight She also repeats the A note as it issues from an organ and when sung This peculiarity of the ear becoming awakened first to certain tones, is most frequently explained on the supposition that the terminal ends of the nerves are in communication with its individual vibrating fiber, each fiber responding to but one tone and independent of each other as the keys of a piano, but that of these fibers, one or more as the case may be, is the most active, free and healthy and therefore the sooner responds to treatment It can also be explained on the telephone theory of the production of the sensation of hearing In the ordinary telephone we find that by increasing the external resistance we can blot out certain tones, and that by shortening the length of the wire or increasing its cross section, that these tones gradually appear more distinctly as the resistance is diminished Applying the same thought to the ear, the remedial effect of the treatment is to relieve the nerve of its external resistance, the inefficient conducting apparatus, and that although the labyrinth participates early in the improvement, yet certain notes being more easily perceived by the cerebral center—just as the telephone translates some sounds better than others—are the first to appear as conscious impressions of hearing, while others take a much longer treatment to develop, appearing only when the external resistance is much diminished or at a minimum My belief as to the favorable effect is, simply, that in many cases of deafness occasioned, probably, by the want of the functional activity of the internal ear structures, the ear fluid becomes more or less irregular in density, and of a somewhat unyielding consistency—the fluid being less liquid and because of gravity it becomes more dense along the lower borders, by reason of the natural attraction of the solid tissues for the more dense particles, it becomes more consistent in approximation to all the surrounding membranes In consequence of this, adhesions more or less firm appear and bind the somewhat thickened fluid particles to the otoliths and membranous linings, the semicircular canals and the cochlea This process is probably twofold, not only as a consequence of disease, but also the result of an increased pressure exerted on the fluid by the forcing inward of the stapes and membrane of the round window Undoubtedly in some cases, the fibroplastic changes occurring in the middle ear extend early to the internal ear and produce an effect there precisely as portrayed above These pressure changes and those brought about by functional inactivity, as well as those produced by the extension of fibroplastic inflammation, all tend to thicken the labyrinthine fluids, to vary the density of different parts—increasing all parts in immediate approximation with the lining membrane—and also by their effect on the nerve, dull its sensibility, and by affecting the blood vessel supply reduce the normal nutrition

The massage properly applied relieves the pressure on the internal ear, causes an active disturbance and circulation of the labyrinthine fluids, stimulates the peripheral ends, as well as the body of the auditory nerve, and improves the blood circulation

So confident am I now in regard to the treatment of labyrinthine disease, that whenever I can find good bone conduction I feel that there is no insuperable obstacle in the way of improving the hearing I consider that if the nerve center, the nerve itself, and the nerve terminals be intact, that there is often not only hope, but fair reason for believing that the treatment will be successful even when the other structures are involved The problem is, so to treat the ear as to allow external sounds to, in some manner, reach the terminal endings As indicated before, massage applied as outlined here, also exerts an effect on the Eustachian tube The constant to-and-fro motion of the ear membrane and of the middle ear contents forces down into the closed Eustachian tube a column of air which acts as a wedge and, while each motion of this column is imperceptible, it will be found by experience that few indeed will be the cases of such closure which do not succumb in time to this treatment

The method is one so easily applied, so devoid of pain and discomfort, so rational as to its application, and promises so much in fields which have up to the present been practically inaccessible, that I feel sure that if used fairly and impartially it will commend itself more and more as we grow experienced in its use I believe ear disease will lose much of its stubbornness and the treatment much of its unsatisfactoriness as this method is developed I do not believe that my method is by any means perfect, but hope that with the aid of other workers in this field of medicine, we may in a few years be able to present such a system of ear therapeutics founded upon a rational mechanical basis as will serve to relieve thousands who by our present methods are incurable

DISCUSSION

Dr F T Rogers, Providence, R I—said that his experience in the use of phono and pneumo-massage prompted him to add his testimony to the inefficiency of the treatment He had used it for several years, making as critical a study of each case as he was able, and he had not seen improvement in over 1 or 2 per cent, while in a larger percentage there was actual impairment of hearing In perhaps 6 or 8 per cent there was partial relief of tinnitus The theory of aural massage is a fascinating one, but we should not forget that in carrying it to a greater degree we' are advising as a therapeutic measure a procedure which causes boilermaker's deafness It is a method of treatment which by most aurists has been used only to be condemned, and Dr Lautenbach is to be congratulated upon obtaining results which have not been verified by published reports of others

Dr J S A Nichols, of New York—stated that his experience with pneumo massage had been disappointing, and it had been rather extensive It was true that improvement took place, but in the vast majority of instances it was only temporary, and the patient returned after a time with tinnitus and hearing unimproved In one class of cases, massage was certainly contra-indicated—those where there had been a suppuration with a subsequent cicatricial membrane In regard to the removal of the ossicles the sum and substance of all the discussions seems to be that the improvement in hearing was not permanent, but when healing took place the hearing was as bad or worse than formerly

Dr Alderton, Brooklyn—Reported a case of removal of hammer and incus in a young lady, the subject of chronic suppuration, in which the suppuration was cured and the whisper advanced from two feet to twenty-two feet This improvement has kept up and the patient has been under observation for three years The Doctor deprecated the operation of ossiculectomy in cases of chronic catarrhal otitis media, but recommended it very highly in cases of chronic suppuration of the middle ear, where the tuning fork reactions, etc, showed the internal ear to be in normal or good condition, and where the hearing has been so reduced as to warrant the supposition that operative interference can not make the hearing worse and must, if anything, make it better

THE SURGICAL TREATMENT OF CHRONIC SUPPURATING OTITIS MEDIA

Read in the Section on Laryngology and Otology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895

BY J H BRYAN, M D
WASHINGTON D C

It is not my purpose in this short communication to go extensively into the subject of the management of cases of chronic suppurating otitis media, but only to emphasize a form of treatment that has of late received a decided impetus, and which in many cases offers us the only rational treatment for this obstinate affection, one that is considered so unsatisfactory by many that we, who have these cases to treat, are condoled and sympathized with for being willing to devote so much time in the treatment of affections, the final issue of which is so uncertain

Much depends upon the seat of the inflammation, whether it is in the epitympanic or in the lower tympanic cavity, they being characterized by somewhat different symptoms In suppurative inflammations affecting the epitympanic cavity or attic, the perforations are situated in the membrane flaccida or the membrane of Shrapnell, and they are situated either anterior or posterior to the short process of the malleus Perforations situated in the membrana always mean caries of the ossicles, which may also be associated with caries of the surrounding walls of the middle ear Owing to the high situation of these perforations, drainage is not readily obtained, and a radical operation here is therefore more frequently called for than in those cases where the inflammation is confined to the lower tympanic cavity, in which case the perforation is generally situated in the anterior or posterior inferior quadrant of the membrana tensa, and permits of much freer drainage While caries is frequently the cause of the prolonged suppuration in this form of abscess, it is not so generally present as in those cases where the inflammation is confined to the attic In nearly all cases of prolonged suppuration of the middle ear, the ossicles will generally be found to be in a more or less state of caries The bonelet most frequently found diseased is the incus, then the malleus, and finally the stapes which has the power of resisting attack longer than the others With the exception of its head it is rarely affected

If after giving the patient a fair trial of all the well-known methods of instilling and insufflating antiseptic medicaments into the middle ear the suppuration still continues, then it is our duty to resort to more radical measures which consist in removing the necrotic membrane with its carious ossicles The aurist must decide for himself when he has exhausted the milder measures before subjecting the patient to an operation I believe in many cases the sooner it is done the better, as it is our duty to arrest the suppuration in this cavity as soon as possible, by so doing we not only preserve the hearing, but prevent the serious sequelæ of this affection that so frequently result disastrously to the patient's life

The operation for the removal of the membrana tympani and the ossicles removes all septic material from the middle ear, permits of freer drainage, and enables us to apply the antiseptic lotions directly to the inflamed mucous membrane of this cavity

The duration of suppuration after the excision of the diseased membrane varies in different cases, but depends to some extent upon the length of time the abscess has existed, and the depth to which the carious process has extended into the surrounding bony walls In the case I have to report, the discharge ceased at the end of a week, and at the expiration of three weeks after the operation the drum membrane had been almost entirely reproduced, only a small opening remained in the upper part of the membrane about where the short process would be if present

While in many cases of partial destruction of the membrane it reproduces itself with great rapidity, still such a rapid redevelopment after total excision as in this case is unusual The cessation of suppuration can be explained by the fact that caries was limited to the ossicles and the most superficial cells of the attic

The benefits to be derived from this operation are well illustrated in the report of the following interesting case

Miss —— consulted me Sept 1, 1894, giving the following history she stated that her general health has always been excellent until the present time, when about 10 years of age she suffered from an abscess in the left ear, the discharge from which continued for about six months, and when this ceased she was quite deaf Since that time she has had frequent inflammation in the left ear, accompanied by pain, when she caught cold, but not going into the suppurative stage until the present attack which commenced about August 1 of the present year At this time she was not in very good general health This attack began with severe pain in left ear accompanied by nausea and giddiness, but there was no discharge until seen by me September 1, when pus was observed for the first time On examination, there was found to be a diffuse inflammation of the external auditory canal due to furuncles, with a small quantity of pus exuding from the canal She complained of intense pain both in the external auditory canal and in the deeper parts of the ear, radiating in front and at the back of the auricle over the mastoid region There was some swelling in front of the auricle just above the tragus, but there was no pain or tenderness over the mastoid region The swelling in the external auditory canal was freely lanced and hot fomentations applied This was not followed by much relief as to the pain which seemed to increase and it was accompanied by nausea, vertigo, double vision and vomiting Although the swelling in the canal subsided somewhat after the scarification there was still too much tumefaction in the deeper part of the meatus for the membrana tympani to be visible The next day, however, after the continuous applications of hot fomentations there was a profuse discharge, followed by great relief as to pain and the other threatening symptoms With the appearance of the pus secretion the swelling in the canal continued to subside, and a polyp about the size of a large pea was observed blocking up the canal This was removed with the snare October 5, and it was found to spring from the middle ear, projecting through a perforation in the membrana Shrapnelli, just posterior to the short process of the malleus The removal of the polyp was followed by a free discharge of thick caseous pus Two days after the removal of this growth I removed a large cholesteatomatous mass from around the perforation which was pressing against the drum This was followed by marked relief as to the pressure symptoms which up to this time were still very marked The membrane was deeply swollen and congested, especially in the region of Shrapnell's membrane in which the perforation was confined

The secretion of pus continued quite profuse and caseous in character for about a week or ten days after the removal of the polyp, but under the continued use of hydrogen dioxid it gradually diminished in quantity, and became more fluid in character On mopping out the canal with a cotton tipped probe, rough bone was detected around the margins of the perforation which had increased somewhat in size since the subsidence of the inflammation The naked probe failed to reveal any rough bone After treating the ear locally for six weeks with antiseptic lotions with no material change in the flow of pus, it was deemed advisable to remove the necrotic membrana tympani and the ossicles which were believed to be the seat of the caries

November 9 Before the patient was sent to the hospital the hearing distance was as follows watch heard only on contact, whisper voice not heard, loud isolated words were heard with difficulty at five feet, tuning fork, bone conduction longer and louder than air conduction

November 15 The patient was admitted to the Garfield Hospital, and on the same day under chloroform anesthesia the necrotic membrane and ossicles were removed according to the usual well recognized method Owing to the adhesions that had formed between the drum membrane and the walls of the middle ear, and the profuse hemorrhage, its removal was attended with some difficulty The hemorrhage was finally checked with a 4 per cent solution of cocain There was only a small portion of the incus found, the remainder having disappeared, and the head of the malleus was honeycombed by the carious process The stapes, as far as could be ascertained, was in good condition and was left in position After the removal of all diseased tissue from the middle ear, the canal was mopped out with a solution of bichlorid of mercury (1 to 6000) and the canal lightly tamponed with sterilized cotton

November 16 During the night there was considerable pain which passed off toward morning, and also some nausea and vertigo The discharge during the night was sufficient to necessitate changing the tampon twice

The ear was cleansed daily, iodoform and boric acid insufflated, and the canal tamponed

November 21 She was well enough to leave the hospital, and came to my office for treatment There was very little discharge present, not enough to moisten the tampon The giddiness still remains, but to a much less degree, complains of a tremulousness and difficulty in getting a deep inspiration Hearing distance for isolated words, conversational tone, sixteen feet, watch heard at one inch, Galton whistle heard sixteen feet and over

November 27 No discharge, giddiness has entirely disappeared The drum has been reproduced to more than two thirds of its full extent

December 5 Owing to a severe cold which the patient contracted, there has been a slight discharge of mucus through the small opening in the membrane, which gradually passed off under the local applications of salicylic acid, gr xx to alcohol ℥i

May 8 There has been no return of inflammation and the patient is enjoying comfort with a comparatively serviceable ear, the hearing distance for the watch being two inches, and for the voice, conversation tones, about five feet

This operation offers many advantages to the patient when the caries is confined to the middle ear cavity and the superficial cells of the attic, but when the trouble is more deeply situated, as in the deeper parts of the attic and antrum, then the more radical operation of Schwartze, Von Stache, or some modification of these must be resorted to

818 17th Street

DISCUSSION OF DR TURNBULL, LAUTENBACH AND BRYAN'S PAPERS

Dr H V Wurdemann, of Milwaukee, Wis, in opening the discussion said, the discussion of subjects such as dealt with in the papers of our colleagues, Drs Turnbull and Lautenbach, is apt to resolve itself into an experience meeting I can only corroborate the frank statements of the former gentleman as to the prognosis to be given to patients regarding the results to be achieved by treatment, in fact, on the acceptance of every patient for treatment of chronic aural catarrh, I give a brief clinical lecture on the natural history of this disease and tell what may be expected, judging from the percentages of cures or of cases in which relief is given from previous experience of myself and others It seems to me, however, the results of treatment by the various forms of massage are better than those given by Dr Turnbull My experience has been that fully one-half the cases that apply within a year after the beginning of tinnitus are practically cured by a course of treatment Others are greatly relieved and fully 75 per cent of all cases in all stages acquire benefit by simple treatment However these cases should receive continuous treatment for a sufficient length of time to remove nasal and pharyngeal congestion or catarrh and to secure patulency of the Eustachian tubes The patients are warned that it will be necessary for them to return in the spring and fall of each year for a few visits when this has been obtained, after a dozen or twenty-five treatments Such that do are benefited and their disease held in check in the greater majority of even the worst cases I have patients now under treatment who have been under my care for six years, and who hear as well or better than they did when they began with me, even though the disease, before the inception of the treatment, had been progressing We can not rely upon one form of treatment to the neglect of others There are several kinds of massage, i e, with the Siegel ‘otoscope,” the Luca spring probe, and direct mas sage with a cotton-tipped probe applied to the short process of the malleus, and internal massage made after the method I described one year ago before this Section at the San Francisco meeting (See Journal of the American Medical Association, Oct 13, 1894) By this method the administration of vapors of various natures is combined with vibratory massage of the Eustachian tube and lining of the middle ear, the drum-head and ossicles by intra-tympanic massage through the catheter Attention to the nose and throat has been made in all these cases, in our lake climate there is a class of cases coming under the head of "apex catarrh" as described by Howard Straight, of Cleveland, in which there is congestion of the apices of the lungs and slight chronic bronchitis in connection with the catarrhal trouble of the upper air passage These are greatly benefited by the administration of creasote in moderate doses I find that nitro-glycerin in some cases has a marked influence on diminishing tinnitis and vertigo, and is worthy of trial In regard to "phono-massage," as described by Dr Lautenbach, would say that my experience has been limited and on account of the diagreeable effect of the sounds of the vibrometer in some cases the patient has absolutely refused to go on with the treatment after one sitting The middle ear catarrh is certainly amenable to mechanical treatment in the majority of cases in which the labyrinth has not been involved In the latter cases I am skeptical as to the results to be obtained by any form of treatment and I am sure these cases will always prove to be incurable A certain proportion of cases where the middle ear is alone involved or where there is but little sclerosis of the labyrinth after due trial for sufficient length of time, i e, for several months of simple treatment by pneumo-massage and vapors, together with attention to the upper air passages, are subjects for operation I have had a number of beneficial results from operations on this class of cases There have been several dismal failures, one of which I reported to this Section at the Detroit meeting (See Journal of the American Medical Association, Oct 22, 1892), in which my subject was made stone deaf by the operation In another, I failed to extract even the malleus, which on account of the bleeding and narrowness of the canal was dislocated into the attic and could not be removed I can not ascribe this to want of experience for I have done this operation over sixty times, the greater majority of the cases, however, being in chronic suppuration of the middle ear I wish to call attention to the difficulty of the operation and to the necessity for proper knowledge of the anatomic relations of the parts In many cases the operation is done chiefly by the sense of touch, on account of profuse bleeding, which is especially noticeable when the patient is under ether anesthetization

Dr S MacCuen Smith, of Philadelphia—The treatment and care of patients suffering from a chronic non-suppurative inflammation of the middle ear has long been a perplexing subject, and upon which the literature has been very voluminous, however, the methods of treatment as advocated by various authors and authorities have been so contradictory in their application, and vary so markedly in the apparent results obtained by different investigators, that we find a majority of the medical profession of to day just about as skeptical of the benefit to be derived from treating this class of cases as they were in former years Nevertheless, within the past few years some notable advances have been made in the way of treating the large and increasing number of our population afflicted with a chronic catarrh of the tympanum

From the paper just read by Dr Turnbull, we must all be impressed with his earnest effort to show that considerable has been accomplished in the way of operative interference in this class of cases Within the past few years I have excised the membrana tympani, malleus and incus, one or all, in a large number of patients, and I must say that my experience thus far as to the benefit derived therefrom has been on the whole quite disappointing This large series of operations was undertaken purely as an experimental matter with a hope that I might be able to contribute some practical information on a subject that has its pro's and con's ardently advocated in almost every medical meeting the world over To an extent at least, I think I have succeeded in establishing a few facts, although sufficient time has not yet elapsed to enable me to make positive assertions After operations of this character almost every case will be greatly improved in hearing, but this as a rule steadily decreases until the patient is in about the condition he was before the operation Some cases have been reported in which the hearing power was considerably reduced below the point it recorded before operation, but my experience does not bear this out In a few of my cases the improvement in hearing has continued over a period of three years or more, and I have every reason to believe this improvement will be permanent

I am familiar with two of the cases quoted by Dr Turnbull, and am sorry that more of my patients did not receive similar benefit Not long since, a patient upon whom Dr. Burnett operated (the wife of a physician) came under my notice and I was much impressed not only with the great improvement in hearing she had maintained for a period of two years, I think, but also her entire freedom from tinnitus and vertigo In conclusion, I would say that I believe the operation under consideration is capable of giving good results when proper cases are selected for its application That inasmuch as the percentage of patients are so very small, in which the hearing is materially benefited, we are not often justified in advising the operation when deafness alone is the only indication for interference However, I believe the operation to be a sound surgical procedure when it has for its object the relief of severe tinnitus and staggering aural vertigo, of course after other recognized methods of treatment have failed to give relief

I wish to say that I have never seen any alarming symptoms or complications accompany or follow this operation As regards the efficiency of pneumo-massage, as advocated by Dr Lautenbach in these non-suppurative cases, my experience has been rather limited, but judging from the results of several of my professional friends, who have had extended opportunities for observation, I am inclined to believe this method of treatment to be a good adjunct to the general line of treatment, of more or less value, but like most agents, quite limited in its usefulness

Mr Chairman, in answer to the note sent you by one of my hearers, in which the question was asked "Can you see the stapes in every case, and in what percentage of cases can it be removed?" I would say that my experience with the stapes is limited to but one case, and in this its removal or partial removal was entirely accidental, and as the patient suffered from severe vertigo for several weeks afterward, I would not care to have a repetition of the accident, much less voluntarily remove it I have been always been opposed to any interference with the stapes, and believe *that those who formerly advocated its excision have now* entirely abandoned such radical measures

Dr Alderton, Brooklyn—Dr Alderton's experience in the removal of the ossicles for the treatment of chronic catarrhal otitis media, both for the relief of deafness and of tinnitus, has been such as not to warrant him in advising the operation of ossiculectomy in such cases He recalled one case in which the operation was done under rigid antisepsis in which the hearing for the whisper was advanced from one foot to sixteen feet +, and yet considerable post-operative irritation manifested itself, suppuration taking place with more or less periostitic pain When these symptoms subsided the membrana tympani was gradually reformed with return of hearing to the condition previous to the operation, with, in addition, a feeling of great stuffiness in the ear Three several times was the reformed membrana tympani excised with similar results, the patient then being advised to rest content, as the danger of causing mastoid inflammation seemed to increase with each attempt The whisper remained about the same as before the operation, and the feeling of stuffiness in the ear very marked and unpleasant In thinking over the case, were the operator to interfere once more he would by Hartman's chiseling instrument remove the upper and posterior segments of the annulus tympanicus in the hope of preventing the regeneration of the membrana tympani and so maintaining the improvement in the hearing

Alderton, in cases of chronic suppuration strongly advises the removal of the ossicles in all cases that have not yielded within a period of three to six months to systematic treatment and in which the nerve has been found by the tuning fork and Galton tests, to be in a normal or nearly normal condition, the hearing being much impaired but counsels that caution be exercised in those cases in which the hearing is only moderately or very little impaired, since in these cases it is perfectly possible to have worse hearing after than before the operation It then becomes a question as to which the patient most wishes or which is most necessary to him—the integrity of his hearing or the cure of the suppuration, and as we can not promise a cure of the suppuration invariably in these cases, it is wrong to hazard the amount of hearing he still retains In *appropriate cases* coming out of the above indications great improvement can be hoped for In one case, Alderton removed the hammer and incus in a young girl for O M.P C the whisper being improved from two feet to between twenty and thirty feet, the suppuration at the same time being cured, and this improvement has been maintained for over two and one half years

In answer to a question by Dr Fulton, Dr Alderton thought that failure to get the incus in O M C C, though unavoidable in a certain proportion of the cases, was due to the removal of the hammer before first disarticulating the incudo stapedial joint He advised, first, making a flat of the posterior quadrant of the membrana tympani, the inferior border remaining the attached border, thus exposing the incudo-stapedial joint usually, then cutting the stapedius and the articulation The tensor tympani and the anterior and posterior folds should now be severed, the patient's head elevated, the malleus extracted, when usually the incus will come into view, or may be reached with a Hewit or Weber hook, or the incus may be removed before extraction of the malleus Plugging and cocain should be used to control the hemorrhage, ether anesthesia being used

In answer to a question of Dr Würdemann, Dr Alderton uses McKay's or Hartman's forceps for the extraction of the malleus The McKay is used in all cases of narrow or tortuous canal Also, though he has occasionally been successful in its use, he does not think that cocain anesthesia is sufficient in most cases of O N C C, though more apt to be so in case of O.N F C

Dr Alderton's experience in the use of phono and pneumo massage has been rather unhappy, as he has not only failed to benefit his patients but has often produced unpleasant symptoms as vertigo tinnitus, etc

Dr Lautenbach—In regard to Dr Würdemann's results from massage he has as he stated, employed it through the Eustachian tube with indifferent results He has probably used it for a very limited period at each sitting from a fraction of a minute to a minute only When used for such short periods good results are obtained only in the mildest cases. Massage to be effective must be used at varying pressures from 50 to 200 motions per minute, and must be continued for from five minutes in mild cases to as much as one to two hours in old, resisting, adhesive troubles As for Doctor's deaf and dumb brother, it would be most interesting to know whether he hears or feels the sounds spoken of If he hears them I am sure some improvement awaits the proper employment of massage as all of my deaf and dumb patients treated by me within the past year (six in number) show some improvement in hearing

Dr Turnbull in his paper gives us some cases operated upon in whom the watch hearing distance varied from five to seven inches—these patients were suffering with tinnitus and vertigo, unless these last two symptoms were most severe—so severe as to materially interfere with the patient's ability to earn a livelihood or to so discomfort him as to render life a burden, suggesting suicidal thoughts—I would not consider myself justified in performing an operation and risk the loss of an amount of hearing which is rarely present after an ossicular operation A case interesting in this connection is that of Mrs Hunter, who after two examinations by an ear specialist was told that in order to relieve the tinnitus and vertigo nothing else but an operation would suffice When she came to me, in addition to the above symptoms, she showed a marked degree of deafness being able to hear the watch only on contact As the result of phono pneumo massage the vertigo completely disappeared, the tinnitus only appearing in a mild form when she had a head cold, the hearing in the one ear is watch thirty-eight inches, the other thirty-six inches Is it conceivable that this result could have been obtained by an operation? Is it not more likely that even though the vertigo and tinnitus had disappeared, the deafness would have remained? Had massage failed in this case, the ear instead of being injured by the delay, would have been rather improved by it, as the mobility of the joints being increased, the operation can be more thoroughly and carefully done

Dr Turnbull has remarked that he has not known of a case of mastoid disease following or caused by the operation I recall a case of a young woman Miss Ida F, of Brownsville, Tenn, upon whom I operated on one ear about April 1893, and the other ear November, 1893, the extreme constant, uncontrollable tinnitus indicating the operations She left Philadelphia and went to Louisville, Ky, about the middle of December, 1893, apparently in perfect health Shortly after Jan 1, 1894, I heard that she had developed some ear disease, and later on I received a letter from Dr *Cheatham of Louisville*, informing me that she had developed a mastoiditis appearing first in the ear operated upon last, which later affected the other ear Despite prompt opening of the mastoid cells and thorough cleansing and antiseptics, the patient died While I can not be sure there was the slightest direct connection between the ossicular operations and the mastoiditis, I yet have a strong belief that the operation predisposed *to the inflammation* as it deranged the structures so as to render them more susceptible to deleterious influences

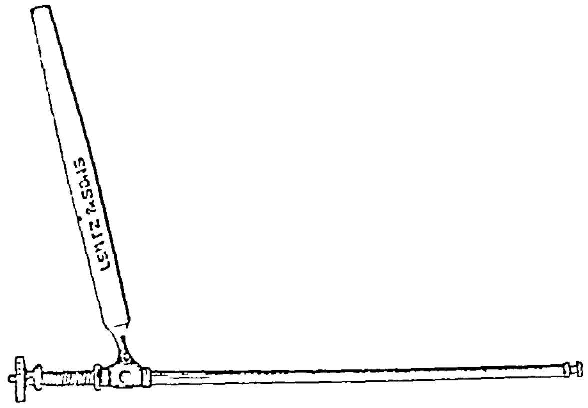
Dr Rogers is quite correct in his assumption that massage may do harm Many of the instruments are crude and unscientifically constructed In this paper I have but spoken of the results obtained from the various machines of my own construction I know of a prominent specialist who has completely abandoned massage methods because of the bad results he obtained from the vibrometer He assures me that in one case he is *positive that* he produced a hemorrhage into the labyrinth, with total loss of hearing, by the use of this instrument

In reply to Dr Nichols' criticism that he can not see how the influences that occasion boiler maker's deafness can be curative in thickened and *plastic middle* ear conditions, I will say that in the one case the noises are continuous loud and oppressive, and act as irritants whereas in phono and pneumo massage, the therapeusis depends upon the regularity of a mild stimulation of the ear structures and its nerve sufficient to gradually break up adhesions and restore the normal circulations, but not enough to result in the throwing out of plastic secretions

Dr Alderton has called attention to a class of cases in which ear massage gives the best of results I refer to cases of old suppurative disease *If the perforation* be filled up by cicatricial tissue or if the perforation be present the effect of *massage* treatment results almost invariably in a *marked* improvement in *hearing*—the improvement being more easily brought about and greater in degree than is present in an intact drum head with an equal degree of eafness—the reason for the greater improvement being the act that the massage exerts its influence directly on the abyrinth through the oval and round windows without the ntervention of the drum head and ossicles Where the rum head has healed over, the cicatricial tissue allows of a reater to and fro motion within the middle ear without the ntervention of the ossicles

Dr Alderton has criticised the proposition that an increase n the circulation of the middle ear results in curative influnces The diseased ear with an increase in the quantity of ibrous and plastic tissues can be compared to a dislocated houlder joint After the joint has been replaced it is kept uiet for a long time and when the ligaments are healed he joint is stiff Effusions have occurred in the muscles nd tissues about the joint, the circulation is impeded To ause absorption of these effete and inflammatory products he joint is carefully exercised and the muscles kneaded n time the circulation is restored and inflammatory prod cts removed the muscles and joint resuming their normal unctions So with the ear, the inflammatory deposits as ell as the deposits occasioned by disuse, calcareous and thers, are present in an ear in which the functional action nd circulation are below normal By increasing the funcional activity artificially, we restore the circulation and reiove the deleterious deposits in just the same manner as he masseur cleaned out the shoulder joint

Drs Alderton and Fulton have both called attention to he difficulty of performing ossicular operations, and of the ability of losing the incus high up in the attic Dr Wurdeiann I believe, has told us of a case in which the malleus lipped up so as to elude removal The danger is an ever resent one unless we have some way of firmly holding the ialleus and then of opening the incudo stapedial joint and hen raising the handle of the malleus outwardly and upard, while the detachment of the malleus and incus is acomplished I succeed in doing this by a forceps I devised ome two years ago, and which I believe is being used by)r Cheatham of Louisville Ky It consists of a rod with a oothed end presenting against a corresponding toothed end f an inclosing tube, the distance between the toothed ends eing regulated by a nut overcoming the pressure of a spiral pring, the action of this spring being to keep the toothed lades apart After the drum membrane is detached, the orceps is inserted and the handle caught firmly as high up s possible, when the nut is screwed down sufficiently tight o hold the handle of the malleus, and yet not so much as to rush it Now having the malleus under control by cutting he tensor muscle and then drawing the forceps slightly utward, raising it at the same time, the incudo-stapedial oint is readily reached and these bones disarticulated—the icus and malleus attachment can then be cut and these ones removed I always use general anesthesia for these perations, never depending on a local anesthetic



That the method does influence the labyrinthine structures vould seem to be proved by the fact of the very favorable esults obtained in perforation cases In order to prove the roposition more thoroughly, I will quote the case of a deaf nd dumb girl, Miss E G , 12 years old who has not been able o hear at all since she had a severe attack of scarlet fever vhen two or three years old She has been examined by Dr Burnett who pronounced it a case of labyrinthine disease, of a opeless nature By the aid of phono-pneumo massage she as been made to hear and even to distinguish many voice ounds and is also able to speak with her family and friends She has developed to such an extent that she is now a pupil n one of the public schools of Philadelphia Again, as a roof of the influence on the labyrinth of such treatment, I ecall a girl, Miss A G H , of Camden, aged 24, who in 1885 ell down a hatchway striking the right side of her head She was unconscious for four or five hours and since her fall has not heard in the right ear In the belief that some of the ossicles had been broken or detached, in March, 1888, I removed the malleus incus, and as these seemed in good position the stapes as well The operation had no effect on the hearing, the tinnitus being but slightly diminished—no hearing in the right ear whatever In 1890 she consulted Dr Knapp of New York, who pronounced the case hopeless In 1894 she returned to me By all tests—phonographic tests with all varieties of sounds—the hearing remained negative There is a secondary membrane present I have been treating her by phono and pneumo massage since then with the result that she hears the watch on contact, and sometimes when just removed from the ear

As before said, I consider this method as offering a new path by which we can accomplish often good results for hearing as well as tinnitus and vertigo, and it does it by putting the ear in a more healthy and natural condition—that it affects not only the drum head and ossicular chain, but the labyrinth and auditory nerves as well, and that this treatment does not in any way interfere with operative measures should they later be deemed necessary

EVISCERATION OF THE EYEBALL

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7-10 1895

BY L WEBSTER FOX, M D

PHILADELPHIA

This operation must not be confounded with abscission, although both are somewhat similar in character The latter operation has been abandoned by the majority of ophthalmic surgeons on account of its risks

Evisceration first consists in excising the cornea and thoroughly removing the contents of the globe, and replacing the vitreous with a glass globe

Abscission of the cornea, as suggested by the older Critchett, was, probably, the best of this dangerous operation In it, no attempt was made toward emptying the contents of the globe

We are indebted to three English surgeons for bringing evisceration prominently before the notice of the profession practically Mules, of Manchester, first operation was performed in October, 1884 Brudnell Carter, who modified the abscission operation of Critchett some years ago, is now one of evisceration's most ardent advocates, while Bickerton, of Liverpool, performs it preferably to enucleation

Frolich was the first surgeon to perform the evisceration This he carried out in 1881 and named it "excochleation " Muldon and Graefe carried on their observations in 1884 Dubanton followed next with a series of experiments

I shall not review the literature on the subject, as it has been done by my friend Dr G Oram Ring, in a very recent article[1] on this subject My remarks shall be limited to my personal experience with some cases

Case 1 —In 1885 I performed the operation twice in the Germantown Hospital, but the reaction was so great, including tremendous swelling of the orbital tissue and eyelids, great pain, and an elevation of temperature (105° in one patient, 105 5° in a second) I felt that discretion was the better practice and removed both glass globes, later on removing the small stumps of the atrophied eyeballs During the summer of 1893, while in Liverpool, Mr Bickerton brought to my notice three patients upon whom he had recently operated The cosmetic effect was so beautiful that I again became deeply interested and gathered renewed courage at his success I also had the opportunity of witnessing the operation at the Liverpool Infirmary by Mr Bickerton, and also the after treatment To see a skilled operator carrying out the technique of an operation is infinitely better than to follow the details of a written description, be it ever so clear and concise

---

[1] Evisceration of the Eyeball" reported in University Medical Magazine, April, 1895

Case 2—The third[2] patient upon whom I performed this operation, June 29, 1894, at the Medico-Chirurgical Hospital, was a young Assiniboine Indian from Montana, now at the Carlisle Indian School He was brought to the hospital by Dr Montezuma to have the eyeballs enucleated on account of pain and much discomfort As near as we could get at the history of the loss of the eye, it was this about three years previously, while on the plains an inflammation of the left eye took place which gradually progressed to an ulceration of the cornea, and finally, to complete destruction of this part of the eye Instead of removing the eyeball, a Mules' operation was performed, under ether The details of the operation were carried out without complication and the patient put to bed

The orbit was examined after twenty four hours—no untoward symptoms were present excepting a slight swelling of the upper eyelid Toward evening the eyeball became somewhat painful, and the patient did not rest well during the night Temperature 102° F , the next day temperature fell to 99° F More swelling of the eyelids appeared, with considerable chemosis of the conjunctiva, but no discharge of pus Chloral and a bromid were given to quiet the pain, and hot fomentations were applied to the eyelids On the third day the conjunctiva became very edematous and protruded between the eyelids, otherwise the patient's condition was about the same as before The internal treatment at this time was hydrarg bichlor, gr 1-32, potass bromidi, gr x, three times daily To the protruding conjunctiva, pressure bandages were applied, which restricted the protrusion The temperature fluctuated about the 99 degree line until July 7, when it fell to normal, and the various inflammatory conditions subsided At the end of the week I removed the stitches from the conjunctiva The sclerotic swelling did not subside for ten days, when the pain disappeared, and at no time during his residence at the hospital did it return

,The operation was entirely successful, affording a beautiful support for the artificial eye, which was adjusted July 18 The artificial eye stood out full and prominent with almost perfect movement—a decided improvement over the old operation of enucleation

Case 3—Operation performed Oct 26, 1894, on a young woman, a patient of Dr Frutchey She had been wearing an artificial eye over the blind eye for several years The result was that she had symptoms of sympathetic irritation, and pain in the partially atrophied eyeball The operation was carried out in detail as above described Upon removing the cicatricial cornea, I found the scleral cavity filled with a bony mass, round and shaped exactly like a small acorn This growth of bone was also a very important factor in the causation of pain The bone was growing larger and the sclerotic coat was restricting its growth, hence the pain The bone was removed without difficulty and given to Professor Laplace for microscopic examination The patient had no untoward symptoms, the temperature ran up to 101 the first day after the operation, and on the third to one degree above the normal line, but no visible change followed—the patient leaving the hospital in twelve days In this case there was no reaction, no swelling of the eyelids and the conjunctiva but very slightly chemotic The artificial eye stands out on a level with its neighbor The movement is perfect, falling but little short of normal

Case 4—A young woman, aged 22 admitted to the hospital on account of an irritable left eye, staphyloma of the cornea, eye useless On account of the repulsive appearance of the eyeball, the patient desired its removal, so as to replace it with an artificial eye The operation was performed under the same antiseptic precautions with little or no reaction no swelling of the eyelids and only a suspicion of edema of the eyelids Owing to a difficulty in matching the right in color, the artificial eye is not quite large enough The movement is exceedingly good

Case 5—Male, age 33 In September, 1884, was struck in the left eye by a brass spring, puncturing the sclerotic, from which exuded a bead of vitreous When brought to the hospital the vitreous was snipped off and the scleral wound was closed by stitching over it the conjunctiva The eye became involved in a general uveitis, with a result of a total loss of vision and slight shrinking of the eyeball I examined this patient about once a year and during the ten years no inflammatory change took place in the eyeball The hyperopia was fully corrected in the right eye and glasses worn On Jan 13, 1892, the following note was made in my case book the sclerotic scar visible, through the conjunctiva no perception of light, total posterior synechia, lens cataractous, no perception of light Tension—1, eyeball manifestly shrunken, no pain nor irritation On Dec 26, 1894, the patient came to see me on account of considerable congestion of the left eye, and slight pain on pressure The result of the examination revealed sympathetic irritation The patient was placed on active mercurial treatment, which reduced the active symptoms, both eyes became perfectly quiet Having had this warning, I advised the evisceration operation, which was performed Feb 2, 1895, at the Medico-Chirurgical Hospital The operation was witnessed by Drs Risley and Carpenter, two members of the ASSOCIATION The case made a very good recovery, with little or no reaction, the only defect is a slight gaping of the conjunctiva and sclera, owing to the central stitches of both conjunctiva and sclera giving way and allowing the glass globe to be visible—the patient is, however wearing an artificial eye, and no inconvenience has become manifest up to the present writing

Case 6—Child, female, age 11 Staphyloma of the cornea of the left eye, due to an ulcer of the cornea three years previously, since then the cornea has developed into a very large staphyloma The operation was performed May 3, 1895 At the present writing the patient is doing well The details of the operation are carried out under ether The eye is thoroughly irrigated with a lotion, which I call formula 1 to designate it from almost the same formula for sterilizing instruments The eyelids are separated with the ophthalmostat The conjunctiva is dissected from its corneoscleral attachment back to about the equator of the eyeball, the muscle not being interfered with, then the cornea is excised—this is best done with a large Beer's knife, as in performing a flap operation for cataract The lower half of the cornea is removed with curved scissors and the contents of the globe are taken out with a small scoop, devised for the purpose Great care is necessary to remove the ciliary body and choroid and the head of the optic nerve, leaving the clean white sclera Mr Carter has devised a rubber bulb which is inserted into the scleral cavity, and inflated with air to produce pressure on the central artery to prevent hemorrhage As this application has not been a success with me, I pack the scleral cavity with sterilized cotton After waiting a few minutes this is removed, and the contents of the scleral cavity again thoroughly irrigated with a hot antiseptic fluid A sterilized glass globe which is best suited to the case, is then inserted with a specially devised instrument, the sclera is split vertically so that the edges may be drawn together and held by fine stitches of catgut, completely hiding the glass ball The orbit is again thorourghly irrigated with the hot solution and the socket packed with sterilized cotton, over which is bound a sterilized bandage, and the patient put to bed

Formula 1 Irrigating fluid

Hvdrarg bichlor	gr 1-50		003
Zinci sulpho-carbolatis	grs xxx	1	80
Aq menth pip	ℨ iv	16	
Aq camph			
Aq destil āā	℥ iv	128	
℞ Sol ft			

The same formula is used for instruments less the hydrarg

In Case 5, instead of using black silk to suture the sclerotic coat, sterilized catgut is used Whether the knot became untied or whether absorption took place too rapidly, causing gaping of the wound and thus allowing the glass ball to press upon the conjunctival suture and cause it to tear, I am unable to say, but from whatever cause the glass ball is visible The patient is now wearing an artificial eye without any inconvenience

When the operation is performed under strict antiseptic precautions very little or no reaction follows, and the results, as Mr Mules states, "are not as disturbing to the normal relation of the parts outside of the sclera" as enucleation Dubanton and Graefe arrive at these conclusions "That the procedure equaled in value enucleation in sympathetic disease, was safer as regards danger of purulent meningitis, can be performed in panophthalmitis, and that, whenever done, a better stump is always secured" If we have in evisceration a method equally as safe as in enucleation, we certainly have in addition the advantage of giving better support to an artificial eye, getting rid of the sinister stare, the enophthalmus and the more perimetric rotation, with no disagreeable mucopurulent discharge so common after enucleation

---

[2] Reported in Codex Medicus Philadelphia, November 1894

1304 Walnut Street

DISCUSSION

Dr S D Risley, Philadelphia, Pa—My attention was favorably called to the Mules' operation by Mr Carter, of London, and I have since performed it in one case with very satisfactory results I regard the advantages of this operation to be

1 Improved cosmetic results as compared to enucleation (He exhibited a photograph to illustrate this in which it was scarcely possible to detect the artificial eye)

2 The patient is much more comfortable after this procedure than after extirpation, for the reason that the tears flow off in a natural way and he is not disturbed by the collection of muco purulent discharge in the orbit or behind the artificial eye as is usually the case after excision

The disadvantages are (*a*), the operation is a much more difficult one and should be done only with careful attention to asepsis and antisepsis Its satisfactory performance is greatly aided by the ingenious instrument devised by Mr Mules for the artificial vitreous and the inflated bulb devised by Mr Carter for arresting the hemorrhage within the scleral cup (Instruments were exhibited by Dr Risley) (*b*), a second drawback is the considerable suffering which the patient must undergo for several days in most cases There was marked edema of lids and chemosis of conjunctiva in my case, with slow pulse and temperature of 99 5 to 101 degrees for four days This was treated with continuous application of cold compresses and lead water and laudanum The chemotic conjunctiva was frequently cut, to allow discharge of accumulated fluid After the fourth day, edema rapidly subsided The swelling could not be regarded as an inflammatory reaction, but was probably due to cutting off the anastomotic circulation by the extirpation of the retina and choroid (*c*), it is distinctly open to question whether in cases of imminent secondary panophthalmitis the procedure is as certain a prophylactic measure as excision, since volumes of the infectious microörganisms might thus be outside the sclera in the lymph channels (*d*), in one case in which I had proposed the Mules' operation but did an excision instead, I found the foreign body which had penetrated the ball, lying near the optic nerve on the outside of the sclera, to which it was still adherent I could but congratulate myself that excision instead of evisceration had been performed

Dr G Oram Ring, Philadelphia, Pa—While the first published case of evisceration was by Frohlich in 1881, Mr Henry Powers claims to have seen Hancock perform a number of such operations before that time I have published recently the history of the case of a child 10 years of age on whom I operated and inserted a glass sphere The reaction was very slight and there was no swelling of the lids, temperature 99 4 on the second day after the operation, falling to normal on the third and there remaining The case was one of increasing antero staphyloma in which eserin and pressure bandage had accomplished nothing The tissues of the face surrounding the eye will, I think, develop much more satisfactorily when such an operation is performed on a young child than after enucleation The cosmetic effect is unquestionable Referring to Dr Hotz's case of sympathetic neuritis following evisceration, and to the two published cases of sympathetic ophthalmia of Dr Cross following the performance of the Mules' operation, I believe, with Mr Carter, that as there had not been primary union of the scleral edges, the irritation was not chargeable to the insertion of the artificial vitreous Should there happen to be extensive infiltration into the deep tissues of the orbit compelling deep incision, evisceration with or without glass globes would, as claimed by Dr Noyes, distinctly hinder the satisfactory progress of the case The perimetric measurements of my case were very gratifying Inward rotation 20 degrees, outward nearly 40

Dr F C Hotz, Chicago, Ill—One of the gentlemen has referred to my paper on "Sympathetic Ophthalmia following Evisceration," in which paper I spoke of the better cosmetic results claimed for evisceration and showed by measurements that as far as rotation was concerned, I was not in favor of evisceration I have continued these measurements since, but regret to say that I have not had opportunity to measure the artificial eye set upon an artificial vitreous I am not yet satisfied that the results of rotation are any better by this method As to the cosmetic effects After examining these photographs I do not see that the sinking condition of the upper lid is much better than after enucleation The only point in favor of an artificial vitreous after evisceration is the fact that the socket is full and consequently there is no irritation from tears, so troublesome after enucleation

Dr E Oliver Belt, Washington, D C—I want to ask if anybody here has had any experience in inserting the glass globe into the capsule of Tenon after operation? It seems to me that there you would get rid of the disturbing secretion and have the advantage of a full orbit Perhaps the only thing that would not be as good as evisceration would be the movements of the eyeball

Dr H Gifford, Omaha, Neb—In regard to the movements of an artificial eye after evisceration, I have made some investigations, and while I confess I have been disappointed in some cases I have found decidedly superior rotation, and this increasing directly with the size of the stump upon which the artificial eye was set When placed upon an atrophic ball, I found it so much better that there was no comparison whatever, and hence can not coincide with Dr Hotz on that point Now there is one other point, about the danger of sympathetic ophthalmia after evisceration that was mentioned by Dr Risley You possibly leave germs in the lymph channels about the eyeball I doubt very much whether a few germs in this locality would make the difference you might suppose, upon superficial examination One germ does not make a sympathetic ophthalmia I think the toxins play a more important part in the development of the trouble A point which may account for sympathetic trouble following evisceration is, that no matter how carefully you do it, you may leave some pigmentary cells or fragments of the retina attached to the optic nerve I have experimented upon a considerable number of rabbits and upon examining them, been surprised to find quite a long piece of retina remaining attached

Dr L J Lautenbach, Philadelphia, Pa—Considering only the mechanical appliances used, the glass balls are compressed spheroids with a surface more or less flattened, and on this there is a small depression It is evident if it is desired to preserve the most perfect muscular motion, that the greatest circumference must correspond to the equator of the eyeball and the flattened surface must be anterior, on account of the inner surface of the artificial eye being flattened, the opposite more curved surface fitting accurately at the nerve entrance of the eviscerated ball Now the instrument here shown does not accurately so place the ball If it does not, the ball may yet adapt itself in proper position or be placed there by the operator This suggests an instrument constructed to hold the ball by a vacuum method until it is inserted It consists of a rubber ball attached to a tube which opens out with a sort of lip of soft rubber of a size sufficiently large to adapt itself to about one third the area of the glass sphere To serve as a handle or support, the lip is made rigid by a backing of brass which extends over the rubber tube as well By extracting the air in the bulb and placing the glass ball in proper position in the cup, the ball being firmly held is easily placed in position with its flat side forward If necessary an expanding speculum could readily be devised to hold the sclera open while the ball is being placed in position Another point which suggests itself to me is the thinness of the glass of which these balls are made This piece which I hold in my hand is about one eightieth of an inch in thickness It is evident that in putting in an artificial vitreous we can at least use a weight of material equal to that of a normal vitreous, and could therefore use glass of one fortieth or even one-tenth inch in thickness The danger of breaking by blows would be lessened, as well as that arising from the attrition of the two glass surfaces, even though the stitched sclera lies between them

Dr R C Hodges, Houston, Texas--It strikes me, from my understanding of the technique of Mules' operation, that Dr Lautenbach has his diagram reversed

Dr L Webster Fox, Philadelphia, Pa—I think Dr Lautenbach does not quite comprehend the operation from his remarks upon the instrument The ball is covered by the sclerotic just as a baseball is inclosed within leather The cases I have examined show it to be one hard body with the sclerotic surrounding it and the conjunctiva in front As to the breaking of these balls, the Indian boy of whom I spoke, received a hard blow and the eye was broken but not the glass ball No ordinary blow would break one I am sure

HISTOLOGIC AND BACTERIOLOGIC NOTES ON THREE CASES OF PENETRATING WOUND OF THE EYEBALL, AND SOME OBSERVATIONS ON CERTAIN BACILLI FOUND IN A CASE OF POST-OPERATIVE PANOPHTHALMITIS

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7 10 1895

BY G E De SCHWEINITZ, M D

PROFESSOR OF OPHTHALMOLOGY IN THE PHILADELPHIA POLYCLINIC OPHTHALMIC SURGEON TO THE PHILADELPHIA CHILDREN S AND METHODIST HOSPITALS

PHILADELPHIA PA

In spite of numerous investigations, the exact nature of sympathetic ophthalmitis is not known, nor is the path of the morbid changes which precede the inflammation certainly ascertained, although the older hypotheses have largely been abandoned since 1881, and the disease ascribed to microbic origin Three more or less distinct theories exist

1 *The "Nerve Irritation Theory"* which, in a modified form, has been maintained by Schmidt-Rimpler thus irritation of the ciliary nerves in the injured eye by means of disturbance in the circulation and nutrition, contrived in a reflex manner, is solely responsible for the disposition to sympathetic inflammation in the other eye The longer the changes have existed and the more widespread they are, the better prepared is the soil for action of the inflammation producing injurious agents, which may be microbic or chemic in nature

2 *The "Migration Theory,"* the chief advocate of which is Deutschmann,[1] who thus states it sympathetic inflammation is a process of microphytic origin, progressing in the continuity of tissue from one eye to another, through the optic nerve apparatus, exceptionally a pure chemic process in the first eye may pass by the same route to the second

3 *The Theory of Infection*, which is inclined to accept microbic influence as the most reasonable explanation of the characteristics of sympathetic inflammation, but which is not committed to the character of the microorganisms, the methods by which they enter the circulation, or the path along which they travel

Perhaps a fourth belief ought to be mentioned, viz , that it is not the microorganisms but their metabolic products passing through the lymph streams which are responsible for the disease

If the ciliary nerve idea is disregarded (and there seems the least evidence in its favor, although it is not disproved), Deutschmann's migration theory is the most attractive Unfortunately, however, a number of researches by the most competent observers, notably Gifford, Mazza, Randolph, Limbourg, Levy and Greeff have failed to confirm his views,[2] and there seems little doubt that in the present state of our knowledge, rabbits, as Greeff asserts are useless in this class of experiments, and probably other animals as well (dogs and guinea pigs) Even if germs are conceded as the cause of the morbid process, it would be practically impossible, as Schirmer points out, accurately to determine the route, unless we could recognize them with the microscope and examine the entire cranial cavity and contents of both orbits in a recent case of sympathetic ophthalmitis in man

At present we must be content with the somewhat indefinite "theory of infection "

To the cases of penetrating wound of the eyeball, causing the conditions usually seen in connection with sympathetic ophthalmitis, I desire to add three observations, bearing upon this subject

Case 1 —Traumatic irido cyclitis, with retained foreign body in the left eye, sympathetic serious iritis of the right eye History H A , a man, aged 29 , eleven weeks before admission to the Jefferson Medical College Hospital, was injured by a piece of steel striking the left eye and was sent for treatment by Dr Hollenbach, of Shamokin

The injury consisted of a large cut through the upper ciliary region, which healed with a puckered cicatrix , the iris was inflamed and bound down to the capsule of the lens, and the anterior chamber shallow , the eye was sightless, slightly shrunken, soft to the touch and tender on pressure

There was moderate congestion of the right eyeball, the circumcorneal zone being tinted with a finer injection of pink hue, faint haze in the lower half of the cornea , few dots of exudate on its posterior layers, and one soft posterior synechia Vision was normal, the field of vision uncontracted and the optic nerve intensely hyperemic These symptoms continued to increase in spite of early treatment, until the full development of serious cyclitis was attained The excitor was enucleated and the usual treatment for iritis continued[3]

Anatomic examination the eyeball, beginning to assume a quadrate shape, was opened and the retina was found detached, the ciliary body thickened, the vitreous puriform, and a piece of steel, 12 millimeters in length and 3 millimeters in width, was discovered lying in the long axis of the eyeball, stretching between the posterior surface of the lens and a point near the optic nerve entrance, entangled in the meshes of the detached retina and disorganized vitreous

Microscopically, the following lesions are present the wound of entrance in the upper part of the cornea is closed with young scar tissue (connective tissue and lymphoid cells), covered on the corneal end by epithelium and pierced in its upper part with large blood vessels Passing backward, this plug of tissue divides the iris into two portions, respectively attached on either side, and terminates in a mass of tissue composed of round cells, spindle cells, leucocytes, pigment granules and blood corpuscles held in a matrix of organizing and organized elements (connective tissue), which passes through the length of the globe and ends in the sclera just above the entrance of the optic nerve In the center of this mass is a groove, marking the position occupied by the foreign body

The iris is infiltrated with young cells, the ciliary body shows plastic cyclitis, with foci of denser infiltration near the ciliary processes and in the choroid (somewhat broken and detached) the same infiltration is sparsely present, but scattered through it, especially in the neighborhood of large blood vessels, are numerous circumscribed collections of densely stained round cells

From the head of the optic nerve proceeds an outgrowth composed of the remains of the detached retina and connective tissue containing numerous round cells In the papilla itself and the nerve, darkly stained nuclei are more numerous than in the normal condition, but this is not a marked feature

The ciliary nerves as they pass through the sclera posteriorly, are much infiltrated with young cells lying within the nerves and surrounding them , also with many pigment granules from the choroid

Summary Adherent corneal cicatrix, plastic cyclitis, with infiltration of the choroid (malignant uveitis) , inflammatory exudate in the vitreous , slight papillitis and neuritis of the ciliary nerves

Bacteriologic examination the specimen was not examined for bacteria by culture method , but microscopically in suitably stained section microörganisms are not to be found

Case 2 —Lacerated wound in the upper ciliary region, irido-cyclitis and cataractous lens of left eye, sympathetic uveitis of right eye marked constitutional disturbance History G W W a man, aged 57 nine weeks before admission to the Jefferson Medical College Hospital, was struck in the left eye by a fragment of stone causing a wound in the upper part of the cornea, and came under the care of Dr G H Woods, of Pine Grove Mills

---

[1] Ophthalmia Migratoria Hamburg und Leipzig 1889 also Beiträge zur Augenheilkunde x Heft 1893

[2] The accuracy of these is again asserted by Deutschmann in a recent critical review of the subject Beiträge loc. cit

[3] The ultimate result was cure in a month and more than a year after the inflammation the eye was entirely normal

The patient was refractory, and in spite of his physicians' advice, exposed himself to inclement weather Severe iritis followed, which under Dr Wood's treatment subsided in about two weeks Then a relapse occurred, associated with several styes upon the upper and lower lid, vision rapidly failed, and in the fourth week after the accident the right eye began to show signs of inflammation and disturbance of vision From the very first, the patient suffered from violent headache and began to lose flesh The urine contained a trace of albumin Slight derangement of intellect was noted eight weeks after the accident

When he came under my care in the Jefferson College Hospital, the following notes were made V of O D equals qualitative light perception, pupil semi dilated from use of atropin, a ring of pigment on capsule of lens, iris thickened and discolored, numerous dots on posterior layer of cornea, lens partially opaque, and vitreous full of dark opacities V of O S equals light perception, T slightly minus, marked ciliary injection, lens cataractous, anterior chamber deep, wound in the upper part of the cornea, extending up and in through the ciliary region for 1 centimeter, and iris prolapsed into the wound and adherent to its margins

The patient had suffered much pain and had lost forty pounds in two months He was demented and suffering with various hallucinations, there was almost complete anorexia He was emaciated, the skin was harsh and dry, the tongue heavily furred, the bowels obstinately constipated, and the urine contained a trace of albumin

The left eye was enucleated, after consultation with Dr W Thomson and the patient put upon mercurial inunctions, potassium bromid, and hyoscin at night to control talkative delirium The general condition vastly improved, but practically no change for the better had occurred in the right eye when he left the hospital, six weeks later

Bacteriologic examination Dr D Braden Kyle very kindly attended the operation, and as soon as the eye was removed he inoculated, with the usual precautions, serum and glycerin gelatin agar tubes, 1 from the divided end of the optic nerve, 2, from the intervaginal space of the nerve These tubes remained sterile, with one exception, in which a growth of cocci appeared, no doubt due to accidental contamination, as other tubes inoculated from the same place failed to show any growth Suitably stained and serially cut sections were entirely free from microorganisms[4]

Histologic examination the cornea and the superficial epithelium are intact, except at the upper corneo scleral junction where there is a purulent infiltration of the superficial layers The neighborhood of the wound is infiltrated with young cells and wandered-in pigment granules

The iris is swollen to twice its normal size and infiltrated with small round cells, a similar infiltration affecting the ciliary body and processes, in the former structure collected here and there into dense foci Scattered throughout these tissues are many pigment granules and branched pigment cells

From here, the process may be traced to the choroid, throughout which there is a diffuse collection of round cells (purulent infiltration) For the most part the lamina vitrea is intact

The retina is detached and although not free from change, as it exhibits scattered areas of infiltration, it is generally of better constitution than would seem likely from the extensive lesions existing elsewhere

The vitreous, where it remains, is a mass of leucocytes

The papilla is swollen, and contains extensive infiltration of leucocytes and darkly stained small round cells Similar cells surround the distended blood vessels and the increased number of nuclei can be traced along the nerve, the process, however, growing less distinct as it departs from the scleral opening In the intersheath may be found inflammatory material

The ciliary nerves as they pass through the sclera are inflamed, and their sheaths contain many inflammatory corpuscles

Summary corneo-scleral wound containing much uveal pigment, malignant uveitis, the choroid exhibiting an early stage of purulent infiltration, papillitis and infiltration of the optic nerve and its sheath, neuritis of the ciliary nerves

Case 3—Penetrating wound through the upper ciliary region with retained foreign body (piece of steel) in the vitreous, beginning purulent irido cyclitis on the fourth day after injury, no signs of trouble in the opposite eye History S M, a man, aged 25, was admitted to the Jefferson Medical College Hospital on account of an injury to the left eye caused by a piece of steel striking the organ There was a lacerated wound in the upper ciliary region, the lens was partially dislocated and beginning to become cataractous, and there was a slight gray infiltration of the wound The eyeball was collapsed from loss of vitreous and slightly tender to the touch, careful palpation revealing a spot of induration in the upper portion marking the probable situation of the foreign body

Many attempts had been made by his fellow workmen to extract the foreign body, or what they supposed to be the foreign body, which was probably some fragments of uveal pigment, and the wound was no doubt thoroughly infected before the patient presented himself for treatment Two days later he gave consent to enucleation, the first signs of purulent iritis being already present Therefore the eye was removed on the third day after injury

The right eye was normal in all respects and showed no signs of sympathetic irritation

Bacteriologic examination Dr D Braden Kyle very kindly consented to be present at the operation, and under proper precautions inoculations into serum and agar tubes were made from 1, the divided end of the optic nerve, 2, from the intervaginal space of the nerve, 3, from the interior of the vitreous, 4 from the area surrounding the wound of entrance, and 5, from the foreign body Dr Kyle reports as a possibility, that the material from the sheath of the nerve may have come in contact with the nerve itself during the act of inoculation, although precautions were taken to prevent this He also states that the interior of the eye was exposed a little longer than is proper to insure the absence of infection from without

Growths appeared in all the tubes, which proved to be staphylococcus cereus albus and staphylococcus pyogenes citreus In one tube, inoculated from the interior of the eye, in addition to the germs already enumerated, the bacillus pyocyaneus was found Suitably stained sections made by Dr Gray, of Washington, exhibit here and there cocci in the purulent areas None, however, are to be found in the optic nerves or the intersheath

Anatomic examination when the eyeball was opened, the foreign body was found lying in the upper portion, partly imbedded in the ciliary region and extending backward through the whole length of the eyeball The vitreous was purulent, and there was a collection of pus on the surface of the iris and ciliary body

Microscopically, the following lesions are present the remains of the lens fibers are swollen and opaque and between them lie numerous round cells (inflammatory material) The lenticular remnants are attached to the margin of the iris.

This structure is infiltrated with young cells—leucocytes and red blood corpuscles A similar infiltration is present in the ciliary body and the connective stroma of the ciliary processes, in the latter tissue the infiltrating cells being chiefly situated at the inner layers toward the choroid

The vitreous is purulent, being represented by masses of pus corpuscles and leucocytes

The choroid does not exhibit general infiltration, but in the inner layers of the chorio-capillaris are dense foci of round cells

The retina, detached and broken exhibits in a beautiful manner, disseminated infiltration with red blood corpuscles in its inner and outer molecular layers In places the fiber and ganglion layers are not distinguishable and are infiltrated with pus corpuscles similar to those in the adjacent vitreous

The surface of the papilla is slightly infiltrated and there is some increase of nuclei and round cells in the nerve itself. The intersheath is free from exudate

The ciliary nerves, as they pass through the posterior portion of the sclera, do not appear to be involved

Summary acute irido cyclitis (hemorrhagic and purulent), with inflammatory exudate in the lens, beginning purulent choroiditis, hemorrhage into the retina, slight secondary papillitis

Remarks the following points seem worthy of emphasis

1 The *Absence of Microörganisms* in the two cases which caused sympathetic ophthalmitis, (Case 1 and Case 2), the exciting eyes presenting perfect types of the lesions which are capable of originating this disease

---

[4] Dr Wm Gray writes in regard to these sections 'The technique was carefully guarded by a control stain on other tissues "

Experience in this line of research has differed widely Deutschmann, for example, has rarely failed to find organisms in an eye enucleated to avoid sympathetic affection of the fellow eye, while Randolph has examined a score of such eyes and has succeeded only once in detecting microorganisms He quotes Ohlmann's examination of thirty eyes enucleated under similar circumstances, bacteriologic investigation being negative in all of them Greeff[6] has carefully investigated fourteen cases of resection of the optic nerve, the period between the injury and the operation ranging from three weeks to three months In each instance the operation was resorted to for fear of an outbreak of sympathetic ophthalmitis No organisms were found in either the optic nerve or its sheaths Similar results have been reported by other observers On the other hand, C E Finlay,[7] in a careful examination of the material furnished by Dr Knapp's laboratory had nine positive results from the interior of the eyeball and two from the intervaginal space, in a total of nineteen cases

Two of the cases now reported are another addition to the negative list, and have value from this standpoint, as well as from the fact that all of the details have been carefully observed from the beginning to the end

In the third case, sufficient time had not elapsed to produce the signs of sympathetic trouble, although the microscopic lesions of the injured eye indicate that such a condition would have occurred had preventive enucleation not been performed It is a positive result in so far as finding the germs of suppuration is concerned, both in sections and in cultures made from the tissues immediately after the operation But this is exactly the result to be expected, the organisms were present, precisely as they would have been in any other active suppurative process Furthermore, proof is lacking (Greeff Schirmer) that the germs of suppuration are the active agents in the production of sympathetic ophthalmitis, although it is just these germs that have been most often found, hence the positive nature of the examination loses its distinction

2 The *Neuritis of the Ciliary Nerves*, especially in the first case A similar condition has been found in a number of instances—Finlay[8] ten times out of twenty-five cases and Berger, whom he quotes, nine times out of fourteen cases Brailey[9] sums up his examination of the conditions of the ciliary nerves in sympathetic disease as follows inflammation of the ciliary nerves is not an essential factor in its production Indeed, it is doubtful whether it can ever be a cause, since it is not infrequently entirely absent, both in the exciting and the sympathetically affected eye and may be present in cases of retinochoroiditis, which neither have produced, nor, judging from their microscopic characters, are likely to produce sympathetic disease

3 The *Constitutional Disturbance in Case 2*—headache, fever, delirium, emaciation—almost a typhoid state One of the chief objections to the theory that the metabolic products of the organisms, and not the organisms themselves, set up the inflammation, is the absence of febrile manifestations, which should be present if toxalbumins are at the basis of this trouble Greeff[10] refers to this point particularly, and largely on its account can not reconcile himself with this idea He quotes Pfluger as having seen a case of sympathetic ophthalmitis with violent headache and fever—an isolated instance which he does not regard of value In the present case, observed for a long period of time, constitutional disturbance was a marked feature, and there seems no other cause except the injury to the eye It is not improbable that careful investigation of the temperature, pulse and respiration in cases of sympathetic ophthalmitis would reveal analogous conditions more frequently than the records seem to indicate

Certain Bacilli Found in a Case of Post Operative Panophthalmitis —D S, a man, aged 55, was admitted to the Jefferson Medical College Hospital, Oct 1, 1894, on account of complete cataract of the left eye and beginning cataract of the right, the vision of the latter being 6–9, with large flocculi forming in the periphery of the lens The light field of the left eye was slightly defective upon the nasal side and the central perception not as acute as might be desired The iris reactions, however, were prompt, and the anterior chamber of normal depth The tension was a trifle below the average resistance Extraction was performed, with the usual antiseptic precautions, on October 5, but before the knife was half across the anterior chamber the patient became absolutely unruly The section was quickly completed and the lens delivered, but owing to the spasmodic contraction of the recti muscles, together with the squeezing of the lids together, a large quantity of semi-fluid vitreous was lost The patient, perfectly uncontrolled, twice swept the margin of his upper lid through the incision

On the second day a gray infiltration of the edge of the wound was visible, and in spite of the most active treatment, proliferation of the vitreous occurred, the eyeball becoming intensely hard and a thick whitish mass appearing between the lips of the wound and in the anterior chamber Twelve days later evisceration was performed and the thick purulent mass from the center of the eye was placed in a carefully-stoppered, sterilized bottle for bacteriologic examination The lower half of the cornea, which had remained clear, was similarly treated

Bacteriologic examination Dr D Braden Kyle kindly undertook the bacteriologic examination and isolated a rod-like bacillus, uniform in size, slightly rounded at the ends, which stains easily with any of the anilin dyes, but better with methyl blue There was also a coccus present, which upon isolation proved to be the staphylococcus pyogenes citreus

In order to investigate the matter still further, cultures were sent to Dr E A de Schweinitz, of the Bio-Chemic Laboratory of Washington, for his opinion, and he returned the following report 'The bacilli are from three to five times as long as broad, often growing in chains, or several of them are joined together They grow on beef broth, and after twenty four hours a pedicle is formed on the surface They also grow on gelatin, but do not liquefy it, and form a white film on agar They do not produce gas in the fermentation tube They slowly coagulate milk, and grow on potato, forming a thick, yellowish reticulated layer They liquefy blood serum slowly"

Archives of Ophthalmology vol xxi p 378

[6] Archives of Ophthalmology, vol xxii p 298

[7] Archives of Ophthalmology vol xxi p 457

[8] Loc cit

[9] Transactions of the Ophthalmological Society of the United Kingdom vol v

[10] Loc cit

In order to test the pathogenic character of this bacillus, injections of an emulsion of the surface growth on agar in beef broth were injected into rabbits' eyes by Dr de Schweinitz, in Washington, and by Dr Kyle and myself in Philadelphia, with entirely negative results, no more irritation being produced than would be expected from the slight wound of entrance When, on the other hand, a mixed culture was employed, namely, one containing the cocci, reaction was prompt and the ordinary phenomena of suppuration appeared

Bacilli have been found in panophthalmitis in a number of examinations, in some cases being associated directly with the development of disease from the pathogenic standpoint

Dr S Poplawski,[11] in an investigation of the etiology of inflammation of the eye after injury, examined twelve eyeballs with beginning panophthalmitis and found bacilli in eight of them, always in the vitreous in the neighborhood of the foreign body There were two forms, a small slender form with no disposition to chain formation, and a large long form

In Finlay's group of cases[12] in one instance a bacillus was cultivated both from the intervaginal space and from the interior of the vitreous The patient suffered from panophthalmitis incipiens as the result of a perforating wound in the ciliary region The following is the description which Dr Finlay gives of this growth "The bacillus was about 7 m long, being rather slender In cover-glass preparations, made from the growth in gelatin, they were arranged in zoogleic masses The bacillus was cultivated in gelatin, agar and potatoes In gelatin it developed with the utmost readiness liquefying it with extreme rapidity almost as soon as it made its appearance, when planted in second and third generations the gelatin would be totally liquid in twenty-four hours In a partially anærobic culture (made by pouring a layer of sterilized oil on the surface of the gelatin after making the puncture), the liquefaction took place much slower, not beginning for months, the growth being somewhat peculiar, from the central stem four peculiar processes were given out, which were arranged crosswise, however, the growth was totally liquefied In agar, the bacillus thrived both in its interior and on its surface, in the latter situation it had a peculiar white waxy appearance On potatoes the growth at first was yellowish, but ultimately acquired a chocolate-brown color, resembling somewhat that of the glanders bacillus " The pathogenicity of this bacillus was established by inoculation into the vitreous of a rabbit

Professor Haab has also found a peculiar bacillus in panophthalmitis to which he attributes a specific character

An interesting case is reported by Randolph[13] in a boy aged 6, following a penetrating wound of the ciliary region made with a piece of wire Inoculation and control experiments proved that the organism which caused the inflammation was the bacillus coli communis, which entered either with the foreign body, or, later, through the wound

The present bacillus can not be classed with those of pathogenic character, as experimentation proved its innocuousness The possibility of contamination with pathogenic cocci must be carefully guarded against in these examinations before ascribing the suppuration to the bacilli, because staphylococci may also be present, as, for example, they were in the case which I report

The piece of cornea, which was removed, is of practically normal constitution, the upper margin containing some lymphoid infiltration Suitable stains failed to demonstrate microorganisms in the tissue

DISCUSSION

Dr R L Randolph, Baltimore—I have been much interested in the paper just read, not only on account of its own value but because the author's investigations were made along a path that I have traveled myself during the past two years Panophthalmitis presents a typical picture of a suppurative inflammation, and one would think that as such the staphylococcus aureus or albus, or certainly some one of the so-called pus organisms would be revealed by a bacteriologic examination Such, though, has not been the case Haab and his assistant, Poplawski, report thirteen cases of panophthalmitis, and in every case a bacillus was found to have been the cause of the inflammation Two years ago I reported a case of panophthalmitis caused by the bacillus coli communis, the latter organism being found in the eyeball in pure culture The paper of Dr de Schweinitz just read, also records the finding of a bacillus It is difficult to explain how the bacillus in pure culture is usually found We know that the conjunctival sac is the resting place for various kinds of bacteria, and it is not likely that simply one kind of organism passes into the eye, and that always a bacillus Maybe the bacilli as a class are of a hardier nature and of more luxuriant growth than the micrococci, and the latter, though present in the eyeball, are crowded out and finally supplanted by their stronger brothers It is singular too, to note the fact that the bacilli found in most of these cases are to be regarded as, comparatively speaking, harmless organisms They are not truly speaking pathogenic organisms, and yet when introduced into the eyeball they produce the most intense and destructive form of inflammation When introduced into the conjunctiva the reaction is insignificant These facts among others go to show that there are many organisms other than the so called pus organisms that are capable of producing suppuration, and that organisms ordinarily harmless, possess sometimes marked pathogenic properties

Dr Harold Gifford, Omaha, Neb —The opinion in regard to the cause of sympathetic ophthalmia seems to be changing, as is the result whenever a new theory is found The pendulum is swinging away from the germ theory and I can not but feel that it is a retrogressive step Dr de Schweinitz found foci of inflammation in his cases,—what caused them? What could produce it but the bacteria or the toxins produced by them? In these eyes the germs were not found, but that does not necessarily show that they had not been present If any of you have examined eyes bacteriologically, you realize how difficult it is to find these germs When staining for germs in the tissues, even the tubercle bacilli is very hard to find There are two points to be considered first, in this region wounds are very common Bacteriologic examinations after experiments upon rabbits' eyes, show that the tissues of the ciliary bodies are most excellently suited to the growth of germs As Dr de Schweinitz remarked, a number of these experiments have failed to confirm Deutschmann's results in this matter I failed to find them in any case in the optic nerve region, but did have them in the ciliary processes in large quantities In the other parts of the eye, you will find them comparatively scarce This may indicate one reason why wounds in the ciliary region are so dangerous How can you account for an inflammation which starts in an eye, creeps along and produces all the disturbances that follow upon any ciliary nerve theory? In regard to the germs found in eyes with panophthalmitis, I have been surprised in many cases at not finding the germ I was looking for, but in a number of them did find what looked like Sternberg's diplococcus, more generally known as Fraenkel's I failed to find them in stained preparations In one case I had a short time ago I found pus germs It seems to me a very important point to bring out here, is the resisting point of bacilli You all know that bacilli are more likely to have spores than micrococci, and are more resistant to antiseptics In noting the precautions taken for operations, I find such remarks as this "Instruments dipped into boiling water" or "put into 2 per cent carbolic acid solution" I think we should not be content with less than five minutes' boiling Pus cells may be killed in one minute, but we should not only take account of these germs, but also the possibility of germs that have spores

HEMORRHAGE INTO THE RETINA AND VITREOUS IN YOUNG PERSONS ASSOCIATED WITH EVIDENT DISEASE OF THE RETINAL VEINS

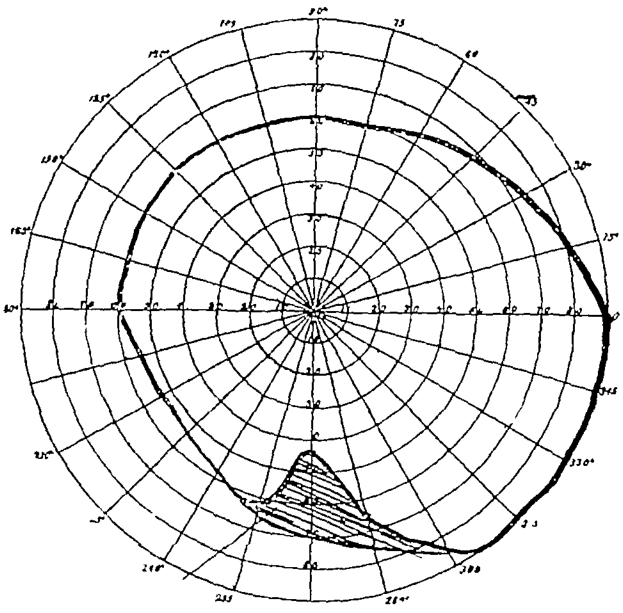
REMARKS ON THE FORMATION OF VESSELS IN THE VITREOUS AND ON THE MIGRATION OF A SUBHYALOID HEMORRHAGE

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore, Md May 7-10 1895

BY HARRY FRIEDENWALD, A B, M D
ASSOCIATE PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS BALTIMORE MD

Hemorrhages into the retina and vitreous are due to an alteration and loss of resistance of the vessels, to changes in the composition of the blood, to disturbances in the circulation or to a combination of these factors In many cases, however it is difficult to determine the immediate defect which led to the extravasation In the interesting class of retinal and vitreous hemorrhages which occur in young persons between the ages of 12 and 24, which have a tendency to recur and to impair vision to a great extent—in these cases the retinal blood vessels have never, so far as I have been able to find in reviewing the literature, been found to present any signs of disease In the two cases which will be reported in this paper, the disease of the retinal veins was evident and important Beside this, the unique observation was made of a subhyaloid hemorrhage migrating from a point above the macular region to a point below the macula, in so doing, it curved around the macula in such a definite manner as to clearly demonstrate the intimate union between the retina and the hyaloid membrane around the macula—a question about which varying opinions have been expressed Another observation of interest was the development of fine blood vessels in the vitreous, which gradually increased and ultimately grew into large connective tissue masses

Case 1—A, aged 15, a healthy robust young man complained (Dec 12, 1892) of slight pain in the eyes He had noticed the occasional appearance of fiery balls before the eyes for several months There was no history of previous eye trouble, excepting a slight blow on the eye about four *years previously*, *this had not been followed* by any permanent impairment of sight His general health had been excellent, but he had had intermittent fever, first about six years ago, and then again slight "dumb" chills during the previous summer The central vision of the right eye was 8-8 and almost as clear as that of the left The field of both eyes was normal, excepting a small defect in the right, at the *foot* of the vertical meridian (see Field 1) There was slight hypermetropia, (0 5 D.s) The ophthalmoscopic examination showed that the left eye was perfectly healthy In the right, there were numerous peripheral hemorrhages, especially in the upper part of the retina These were all in the *form* of small dots and spots, there were no large extravasations The papilla and the central portion of the retina were *normal*, the arteries presented no decided changes excepting slight fullness and tortuosity, but the veins were much distended and the smaller ones were very *tortuous* The patient was seen frequently but no changes were noted until Jan 3, 1893, when a large hemorrhage was found to have made its appearance in the upper part of the retina, its occurrence had been preceded by the appearance of fiery spots On the following day it seemed to have changed its position to a part lower down in the retina An accurate sketch was made at this time and certain other changes were noted (See Fig 1) The large effusion was now situated above and to the temporal side of the papilla its lower edge was about 1 P D from the upper edge of the very distinct macular reflex The effusion completely hid the underlying blood vessels, which appeared sharply broken off at its margin The upper edge was a perfectly horizontal line The lower margin was made up of irregular curves The arteries appeared unchanged, but decided alterations were noted in the veins The vena temp super which was greatly distended, *ended abruptly in two very small and very tortuous* branches At this point there was a curious twist, shown in the drawing, in its course it gave off a large number of fine branches The vena temp infer was not only over-distended, but showed a marked difference in its caliber at various points Soon after leaving the papilla it widened out but became narrower again, before dividing into its two branches The branch running toward the temporal side ended in very tortuous twigs The vena nasal infer was not greatly congested as were the two former At one point it presented a constriction so great as almost to divide the blood vessel, (D) A small bluish spot (A) was seen lying upon the vessel and resembled a little cloud The congestion of the retina was likewise shown by the appearance of numerous fine vessels throughout the retina, one set lay below the macula and was apparently not connected with any of the other retinal blood vessels, (C) The vessels of the superior nasal quadrant were normal and there were *no* hemorrhages in this region V R E 8-8 V L E 6-6 There was a small scotoma between 5 and 10 degrees beneath the point of fixation



Field 1

January 6, I was surprised to find that the large hemorrhagic plaque had migrated to a lower point and was lying directly over the macular reflex, its lower edge was slightly concave and corresponded with the convexity of the upper margin of this reflex (See Fig 2) The hemorrhage was bounded above by an almost perfectly straight and horizontal line, at the nasal end this ran out into a set of linear hemorrhages which united the large effusion with the hemorrhages in the upper part of the retina The area occupied by the effusion two days before was now apparently normal There were dust-like opacities in the vitreous

January 10, the hemorrhagic effusion had sunk still lower and had become divided into two *parts, united by an irregular line* A small portion (see Fig 3 E) occupied the former position in the form of a narrow band, whose lower edge fitted closely to the reflex of the macula in its upper and outer portion The greater part of the effusion occupied a position to the temporal side of the macula and beneath it (See Fig 3, F) It was not regular in form but its upper margin was mainly formed by a straight horizontal line A fresh vitreous hemorrhage had occurred from the upper and temporal portion of the retina (Fig 3 G)

January 12 there was but a fine hemorrhagic line remaining as a margin of the upper border of the macular reflex The line of hemorrhages which united the two parts of the effusion and the hemorrhages in the upper part of the retina, had to a great extent disappeared, only a few points were left to indicate its position A number of white spots were seen among the hemorrhages in the upper part of the retina

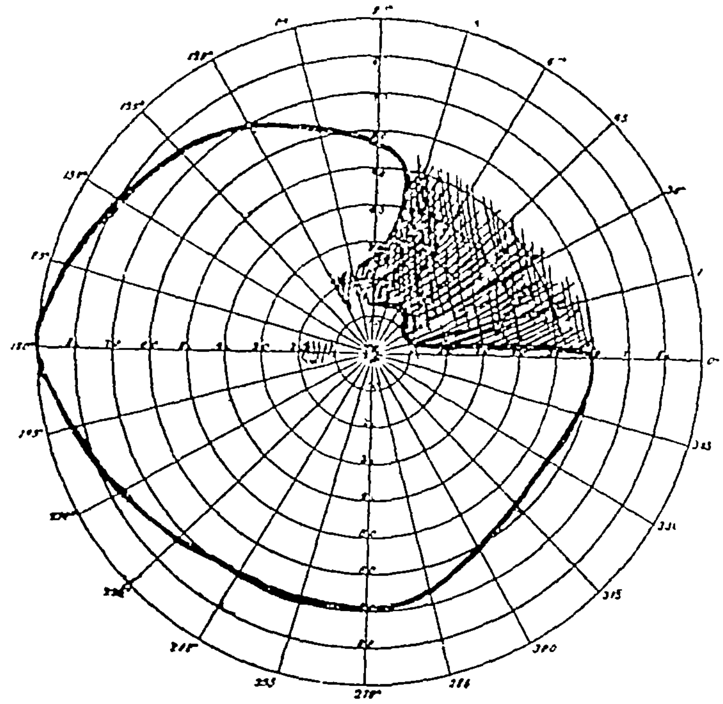
January 16, fresh hemorrhages had again occurred, a fine linear hemorrhage lay in the inner macular region, a large effusion reached partly into the vitreous below (See Fig 4) The vena nasal super presented a fusiform dilatation at some distance (3 to 4 P D) from its origin Central vision was almost perfect, but sight was somewhat disturbed during the past few days by a dark brown crescent-shaped cloud moving before the eyes

January 22, the hemorrhages below the macula had so far diminished in size as to become lines resembling fine blood vessels

January 30, at the point where the vena temp super ended in two fine branches, a veilly formation made its appearance, it was formed of a delicate network of blood vessels, lying in the vitreous (See inserted in Fig 4)

February 11, there was a fresh hemorrhage in the lower inner periphery of the retina, the old hemorrhage below the macula had entirely disappeared, V R E still 8-8

March 5, the vena nasal infer showed peculiar changes About 2 P.D from its origin, it sent off a large number of fine capillary vessels, which formed a meshwork in the vitreous (Inserted in Fig 4, at A) At this point there was the appearance of a bend or twist in the vessel A short distance beyond there were two thickenings, which upon close examination were seen to be twists in the vessel (Fig 4, H H) Beyond these points the vessel became exceedingly attenuated for about 1 to 2 P D, then widened out and divided into fine twigs On one of these there was a distinct round elevation (Fig 4, J) This upon careful observation, was found to be a varicose dilatation, upon pressing on the eyeball, the dilatation visibly *diminished in size* One of the fine branches arising from the vena temp super had become very tortuous and ended in a bunch of blood vessels reaching into the vitreous The vena nasal super was now very tortuous, had marked variations in its caliber, (dilatations and constrictions), and was covered in the periphery by a hazy gray cloud



Field 2

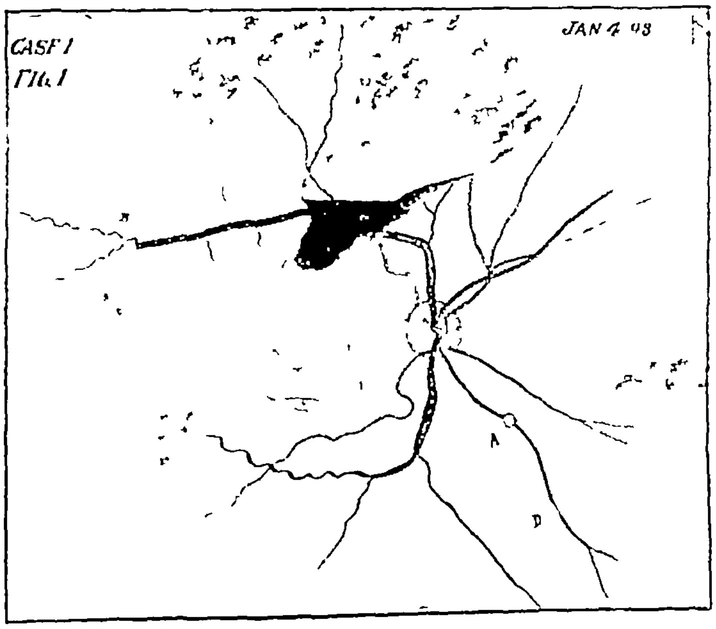
March 28, the vascular veil arising from the vena nasal infer had greatly increased in size and now reached the lower inner margin of the papilla, (best seen with 2 Ds) The vascular formation on the vena temp super had likewise greatly increased in size and now contained some whitish connective tissue V unchanged Since the last visit the patient had had a recurrence of the intermittent chills, on March 17 and 19 they were severe, he then began taking quinin and was relieved

April 7, V R E, 8-6 almost The hemorrhagic spots in the upper part of the retina had almost entirely disappeared, there were no fresh hemorrhages The vitreous still contained fine dust-like opacities

April 21, sight was unchanged until this morning On the preceding day he had been *sparring for some time* While reading the paper in the morning, he noticed the appearance of arrows, (black and green), flying before the eye and then a veil Sight rapidly became worse, so that when examined a few hours afterward he could count fingers at but three feet With the ophthalmoscope it was evident that a large vitreous hemorrhage had occurred

During the next few days the veil seemed to rise somewhat and V L E became 8-50 (almost), by April 23 At this time the hemorrhages were visible on the nasal side of the retina and in the vitreous toward the temporal side and below One of these seemed to have started from the upper, outer part of the retina The vascular formations in the vitreous gradually increased in size On May 18, the one on the vena nasal infer had entirely crossed the papilla and extended beyond its upper outer margin V R E 8-18 partly

Feb 14, 1894, the patient returned after a long absence He informed me that his vision had improved so much that he had been able to see as well with the right eye as with the left But in September, 1893, he had had a recurrence of his malarial chills and his vision had become slightly worse In December, 1893, he had again had a hemorrhage, which likewise slowly cleared up A few weeks ago another hemorrhage had occurred and this had almost completely destroyed the vision of the right eye He could but see movements of the hand in the outer part of the field



At this time, (Feb 26, 1894), he was thoroughly examined by my brother, Dr Julius Friedenwald, who found all the organs healthy, (lungs, heart, kidneys, etc , the urine had been examined a number of times before, with negative result) The examination of the blood showed that "there was a low percentage of hemoglobin, but that the number and variety of the red and white corpuscles were normal The condition was therefore similar to that of chlorosis in the female "

There was a black reflex to the ophthalmoscope in all directions excepting in the innermost part where there was a narrow line of red V gradually improved and the red reflex became larger

May 1, V 6-60

June 22, V 8-36 Slight red reflex in the center of the pupil

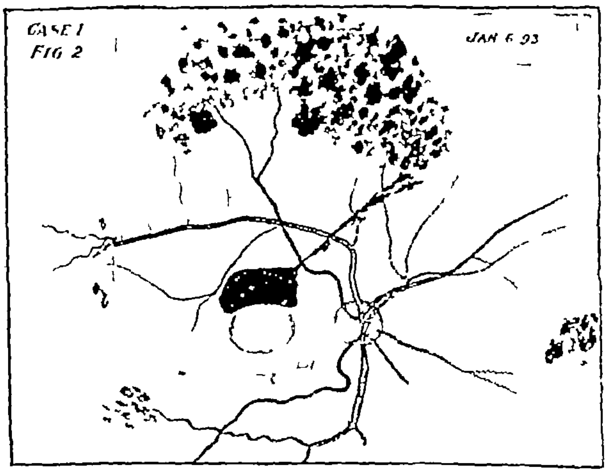
July 21, V 8-12 (partly) The center of the dilated pupil is clear, but the periphery of the vitreous is in great part dark Toward the end of 1894, V again became worse but subsequently cleared though very slowly

At the last examination, (April 18, 1895), V with dilated pupil (atropia), 8-24, with —1 Ds 8-18 and 8-12 partly' The eye now admits of ophthalmoscopic examination, the papilla is fairly clear, there are large masses of vascularized connective tissue in the vitreous, much larger than when last seen, presenting the picture of retinitis proliferans'

Concerning the treatment, of which no mention was made in the above history, we may state here that it consisted at first in the administration of ergot, later of iodid of potassium, of jaborandi and of quinin None of these remedies produced any decided or even appreciable effect on the course of the affection

In following this case, it is evident that the hemorrhages were due to disease of the retinal veins[3] The first appearance of the hemorrages, which were densest in the upper periphery of the retina was associated with a definite sector-like defect in the field of vision, which has never disappeared It is quite probable that this was due to a thrombosis of a small venous branch in the corresponding part of the retina The affection of the veins was demonstrated by the pathologic dilatations and constrictions and by the varicose formation

The fine vascular loops which developed in the vitreous, started from greatly congested veins and at points where there was a twist of the vessel (A and B) While under observation no vitreous hemorrhages occurred at these points, the development of the blood vessels was not the result of a process of absorption of effused blood It is difficult to account for their formation in this case, unless we assume that they resulted from the great engorgement of diseased veins It is scarcely possible that they were an evidence of organization of vitreous opacities, for the opacities which existed at that time were exceedingly fine and slight As in a case which I have recently seen, and which I shall report at some later time, we may regard them as an evidence of vascular disease



CASE I FIG 2

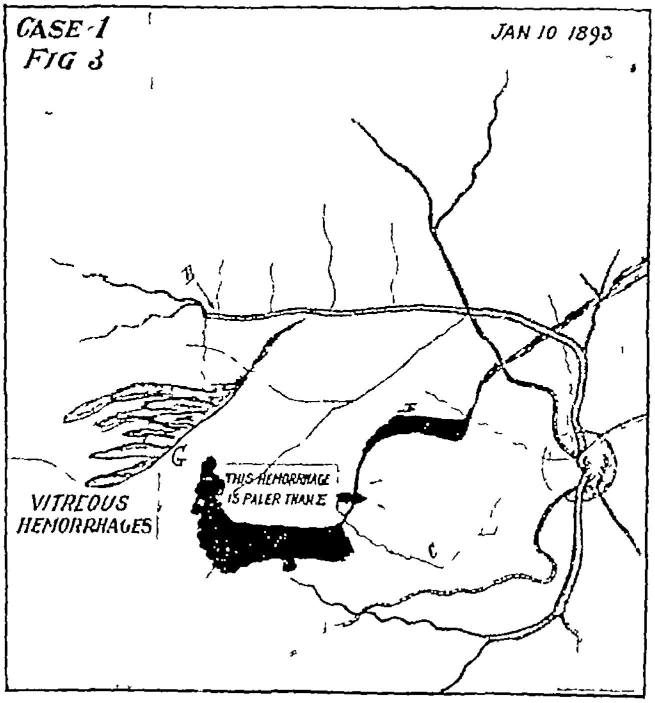
JAN 6 93

The fine, transparent vascular formations gradually and slowly developed into large connective growths, known as retinitis proliferans This affection or rather condition is usually attributed to the organization of hemorrhages in the vitreous (See *Leber Graefe Saemisch's Handbuch*, vol v, p 666) Our case definitely showed that the vascular formation may be the beginning of retinitis proliferans Connective tissue growths have been observed in other cases of juvenile vitreous hemorrhages[4] In these cases the connective tissue was considered an organized blood clot

Concerning the appearance of newly formed blood vessels in the vitreous, we may mention that but a small number of cases have been published and in these the vessels remained stationary or disappeared in the course of time Their development into the connective tissue masses described above, has not been observed[5]

A feature of great interest in our case lay in the subhyaloid hemorrhage Its position between the retina and the vitreous admits of no doubt These cases have recently been collected and studied by Haab,[6] Dimmer,[7] and Hotz[8] The total number of these cases is not large In one respect our case differs from all the rest, namely, in the distinct appearance of a firm union between retina and vitreous around the macula That there is such a firm union in these parts has been assumed by Gunn, Nettleship, Lang and others to account for the circular form which subhyloid hemorrhages within the macula usually take on But this assumption was weakened by the fact that subhyaloid hemorrhages in other parts likewise frequently have a similar form In our case this union was proved by the form which the blood assumed in following the course of least resistance around the macula

Our case undoubtedly belongs to that curious class of juvenile hemorrhages of which numerous cases have been published No definite cause has been discovered for this affection, but a number of etiologic factors such as anemia, constipation, dyspepsia, cardiac hypertrophy etc, have been assumed None of these, except slight anemia, were present in our case



CASE 1 FIG 3

JAN 10 1893

Malaria may have played an etiologic rôle The patient had had malarial fever previous to the onset of the ocular affection and during its course, once a hemorrhage occurred at the same time as the chills In view of the fact that there was no other etiologic factor and that a number of cases of retinal hemorrhage unquestionably due to intermittent fever, have been published, it is proper not to disregard this fact In most of these cases,[9] however, the patients suffered with a severe form of the disease and frequently with marked cachexia

The trauma referred to in the history occurred so long before and was so slight that no etiologic importance should be attached to it

Case 2—R K aged 22, male, consulted me Nov 23, 1890 He had had good eyes and no constitutional disorders excepting measles in 1880, and typhoid fever in 1887 He had never suffered any injury There was slight but chronic constipation Urine was normal He related the following history, which was subsequently confirmed on Oct 14, 1889, while at dinner a veil suddenly appeared before the left eye, and in a little while there was scarcely light perception left He was examined by a well-known oculist who found a vitreous hemorrhage Sight improved, and in about three weeks he was able to distinguish persons and in six, he could read In three or four months he considered the sight restored to its full extent (?)

Oct 14, 1889, V L E, 8 18, V R E, 8-8 In the left field of vision there was a large defect occupying the upper nasal quadrant, evidently due to disturbance of the circulation in the inferior temporal vessels (See Field 2) Ophthalmoscopic examination the right eye showed nothing abnormal in the retina and a fine floating opacity in the vitreous The image of the left eye was very clear, the papilla was hyperemic, as was also the retina (unusually large number of fine blood vessels seen everywhere) A slender pillar of intensely white connective tissue was seen projecting from near the center of the papilla somewhat nasally, downward and forward into the vitreous Through its whole length a few fine blood vessels could be traced At the papillary origin a great number of very fine blood vessels were seen, forming slender loops in the vitreous At the distal end (best seen with + 6 D s), another set of vessels extended far into the vitreous, and at the end of one of these there was a gray vitreous opacity of such a shape as to suggest its being a degenerated blood vessel These vascular loops appeared to be entirely free from any connective tissue The long connective tissue mass with its vascular outgrowths swayed gently to and fro when the eyeball was moved

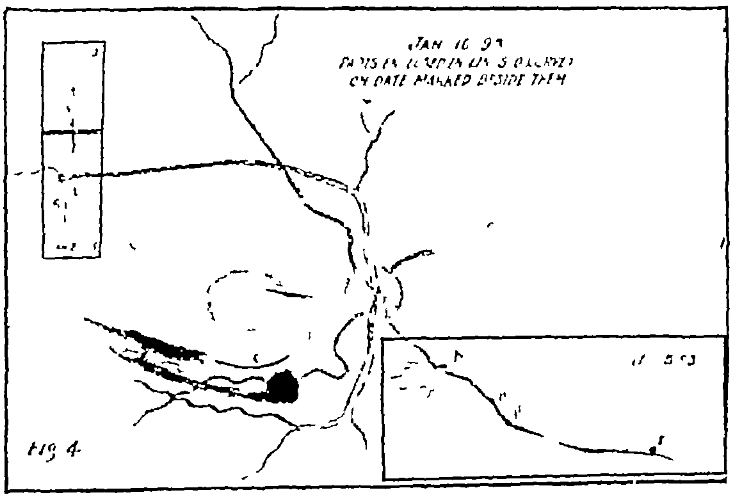


Fig 4.

On examining the retinal blood vessels the following observations were made on the superior temporal vein, about 2 P D from the margin of the papilla there was a red spot, lying directly over the vessel, it was somewhat irregular in form and had a diameter of between two and three times that of the vessel upon which it lay It had something of the appearance of a small hemorrhage with a faint whitish film over its central part On close examination it proved itself to be a varix, upon pressing upon the eyeball its size would diminish until it almost disappeared, leaving only a small gray spot not extending beyond the margins of the vein That there was no optical illusion was proved by the distinctness with which a fine blood vessel which ran into it was seen after the spot had almost entirely disappeared The vein itself showed no abnormality except a slight constriction just beyond the varix, this was apparently due to a gray thickening of the walls

The inferior temporal vein presented a number of interesting points About 1 P D from its origin it divided into two fine vessels which soon united in a large red spot, this had a diameter of between two and three times the caliber of an artery of the first order Beyond this, the vessel extended for a long distance but was exceedingly tortuous Near its origin the vessel sent off a fine macular branch, which in the macular region ended in a small rounded red spot Far in the temporal periphery, a similar spot hung like an apple from one of the veins, a fine white thread, an obliterated branching vessel, extended from it to a spot of choroidal atrophy

These red spots were all small varices, their size decreased decidedly on pressure on the eyeball

In the macular region there were a number of gray streaks and spots (irregular reflexes?), and one little crystal

At an examination about ten months later, no changes were noted in the picture described above

This case is in many respects analogous to Case 1 The vitreous hemorrhage which had thoroughly cleared up when I first examined the patient, must be ascribed to the diseased veins, as was seen in the varices and in the sclerosed vessel in the periphery of the retina No cause can be assigned for these changes

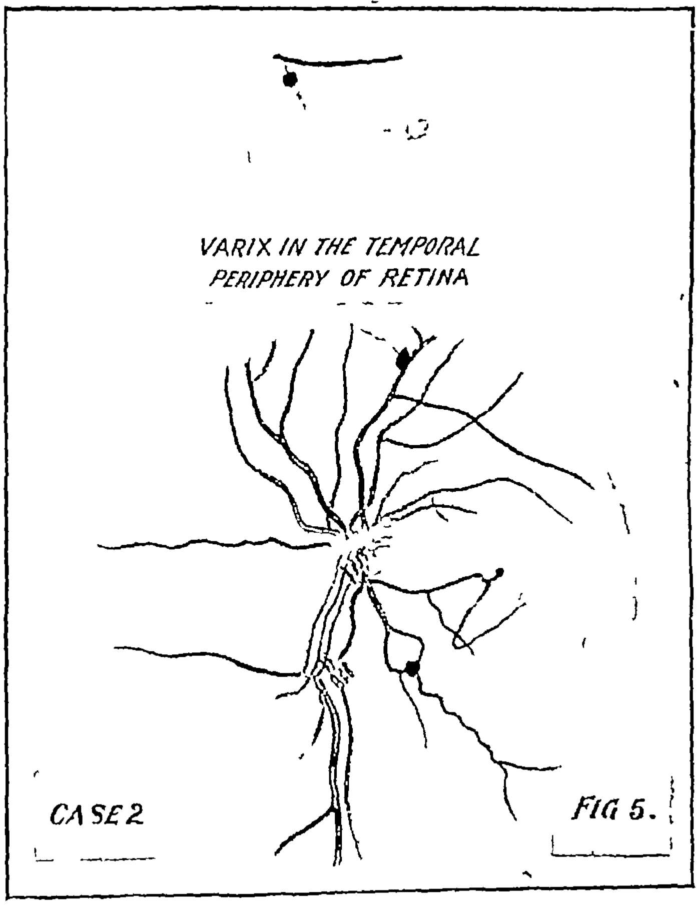

FIG 5.

In this case, the connective tissue in the vitreous was probably of different origin than that in Case 1 It had all the appearance of being a cicatricial band resulting from the absorption of the hemorrhage The development of the fine vessels in the vitreous, as outgrowths from the connective tissue band, may have been due to the same cause or they may have originated independently, as in Case 1

As both of these cases presented such marked evidences of vascular disease, I am inclined to the view that hemorrhages of the retina and vitreous in young persons may often be due to similar conditions Further observation will prove or disprove this view It is but proper to mention that a careful search has not resulted in finding any description in literature quite comparable to that observed in our cases [10]

---

[1] Nieden observed a case of vitreous hemorrhage in which emmetropia developed into myopia (6 Ds) Bericht der ophthalm Gesellschaft Heidelberg 1883

[2] Since the paper was read the patient has been examined a number of times His vision continues to improve August 26 1895 V R E 8-24—1 75 D s 8-S almost At this time there was a clear red reflex in every direction with but few grayish and translucent vitreous opacities, the image *of the papilla was fairly clear* The vessels were normal, or slightly congested as far as they could be followed some disappeared in the white connective tissue formations The latter contained blood vessels which extended *far forward into the vitreous This improvement* gave us great encouragement but unfortunately on Oct 11 he returned with a fresh vitreous hemorrhage, which had again reduced vision to the perception of light

[3] The source of the vitreous hemorrhages under consideration has sometimes been placed in the retina, more frequently in the choroid

[4] Jacobson, Mittheilungen a d Koenigsberger Klinik, 1880, reviewed in Nagel s Jahresbericht for 1880, p 350 Proebsting Arch f Ophthalm XXXVIII 3, p 114 Raab Arch f Ophthalm XXIV, 90 Chodine, reviewed in Annales d Oculistique, Amer Ed 1895 p 287

[5] See Hirschberg Centralbl 1890 p 266, where a number of cases are collected Schutter Centralbl 1881 p 40 Charnley and Fox Ophthalm Hospital Reports X 2 p 193, reviewed in Nagel's Jahrb f 1881, p 424 Jacobi Zehender s Monatsbl 1874, p 255 reviewed in Nagel s Jahrb 1874, 387

[6] Deutschmann's Beitraege, Bd I p 395

Deutschmann s Beitraege, Bd II p 389

[8] Annals of Ophthal and Otology, Jan 1893

[9] These cases have never been collected A brief resume is therefore not out of place

V Kries (Graefe s Archiv, XXIV reviewed in Nagel s Jahrb f 1878, p 231) observed two cases as sequelæ of intermittent fever, in one there was a profuse vitreous hemorrhage in one eye in the other case there were profuse retinal hemorrhages in both eyes

Pennow Centralbl 1878 p 88) (reviewed in Nagel s Jahresb f 1878, p 230) found retinal and conjunctival hemorrhages in a number of patients suffering with intermittent fever

Karpinsky observed retinal hemorrhages in a patient who had had intermittent fever for two or three weeks (See Nagel s Jahresb f 1879, p 226)

Pennow observed retinal hemorrhages in a case of malarial cachexia, (Nagel s Jahrb 1883 p 801)

Landsberg (see Nagel s Jahresb 1894 p 826) reported two cases of retinal hemorrhages due to intermittent fever and occurring during or just after an attack

Jones saw twelve cases of intra-ocular hemorrhages in malaria (N Y Med Record June 27 1885 p 705)

Bull reported seventeen cases of intra-ocular hemorrhage which he ascribed to malaria All of these patients were over 50 years of age Equatorial choroiditis was seen after the blood was absorbed (N Y Med Record Dec 1886)

Mackenzie saw four cases of retinal hemorrhages due to very severe forms of intermittent fever (Lancet 1887 vol II p 497)

Brunt reported six undoubted cases In all of them there was a high degree of malarial cachexia (N Y Medical Record 1888, p 36)

Minor mentions the occurrence of retinal and vitreous hemorrhages as a result of malaria (Amer Journal of Ophthalm 1891 p 243)

[10] Jacobi described varicose tortuosity of some retinal veins in three cases in one associated with the *development of blood vessels in* the vitreous But this appears to have been quite a different condition from that described in my cases (Klin Monatsbl., 1874, p 255 reviewed in Nagel s Jahrb f 1874, p 387)

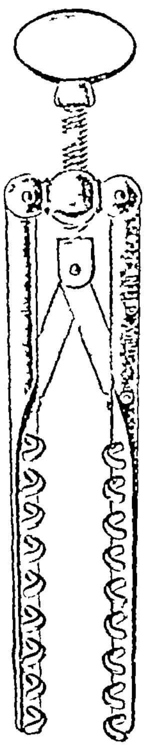
NEW INSTRUMENTS

A MODIFICATION OF MY MASTOID RETRACTOR

BY FRANK ALLPORT, M D

PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE MINNESOTA STATE UNIVERSITY PRESIDENT MINNESOTA STATE MEDICAL SOCIETY, ETC
MINNEAPOLIS MINN

Some years ago I devised an instrument for facilitating mastoid operations It has passed into extensive use, but its utility has been much curtailed by the fact that many instrument manufacturers persistently perpetuate two faults in its construction They make it *too delicate for permanent* strength, and what is still more annoying, make a round or square screw-handle The screw-handle should be flat, for when it is either round or square, the fingers will surely slip in screwing it up after the teeth have become engaged in the wound This defeats one of the prime objects of *the instrument*, which is intended to be tightly screwed up, thus expanding the blades as widely as possible, for the double purpose of affording ample ground for operation, and of controlling the hemorrhage of the soft parts by producing extreme tension These objects can only be obtained with a strong instrument, and a good-sized flat handle I earnestly desire all instrument makers to notice these instructions in order to enable the instrument to accomplish its full amount of good



At this point I also desire to correct an unintentional error occurring in the last catalogue of Chas Truax, Greene & Co, of Chicago, who present a cut of my retractor among their mastoid instruments, under the name of Barth's Retractor Dr Barth, of Marburg, Germany, has, it is true, devised a mastoid retractor, but it differs entirely from the one devised by myself My mastoid retractor was made when nearly everybody used the drill for mastoid operations, and only a small field of operation was desired At present the drift of sentiment favors the chisel for such work, and for this purpose a larger and stronger instrument is desirable I have, accordingly, enlarged and strengthened my retractor, as will be seen by the accompanying cut My old instrument has incurved arms, thus enabling the teeth to lock and be inserted in a small opening The new retractor is intended for larger work, and an incurvation of its arms would lessen its strength, consequently I have had them made straight After the incision has been made, the lips of the wound can be shoved back, and the teeth, which are somewhat separated at the middle of the instrument, easily inserted and the blades expanded It is scarcely necessary to say, that this expansion should be as wide as possible, for the purpose of affording a large field for observation and controlling the hemorrhage of the soft parts

This retractor has also been devised for the purpose of facilitating openings into the cranial cavity at other portions of the skull, for abscesses, tumors, etc

I would remark incidentally, that the principle involved in this instrument can be made useful in operations upon any part of the body where it is desired to hold apart the lips of an incision Different sizes and shapes would, of course, become a necessity, but the principle involved is correct, and would much facilitate many operations

This instrument has been admirably constructed under my personal supervision, by Chas Truax, Greene & Co, 75 Wabash Avenue, Chicago, Ill, where it can be obtained, and I would respectfully request all other instrument makers desiring to manufacture the retractor, to strictly adhere to the model I have endeavored to describe

SOCIETY PROCEEDINGS

Chicago Pathological Society

Regular Meeting, Sept 9, 1895

WELLER VAN HOOK M D, President, in the chair

DR E FRIEND read a paper entitled

SYMMETRICAL GANGRENE OR RAYNAUD'S DISEASE

It is not with the idea of elucidating the etiology and pathology of this rare and *interesting* affection of the skin that I report the following case, which I had the good fortune of seeing, but merely to show the keen observing powers of that most excellent clinician whose name this disease bears and also to freshen the memory of those whose labors in other fields preclude the review of the literature of this subject

Page 29 of Raynaud's original thesis, translated by Thos

Barlow, M D , states "If, as I have attempted to prove, the fundamental fact of gangrene consists in the diminution or absence of oxygen necessary to the integrity of the life of a tissue, the pathogenic conditions of gangrene considered from a philosophic point of view will bring us back to the following cases

"1 Absence of blood dependent on all causes which may attack the normal functions of the arteries (obliteration of them in only a particular case) This condition can be compared to nothing better than syncope, in which the action of the heart is momentarily suspended I propose to call it 'local syncope'

'2 Presence of venous blood, that is to say, of a blood insufficiently oxygenated Continuing to use a term of comparison in the same order of ideas, I will designate this condition, local asphyxia

3 "It is possible that in consequence of an intoxication inexplicable as to its nature, the living cell, although having at its disposal the elements destined for its nutrition, may be struck with powerlessness to profit by them and gangrene results"

In classifying his cases, he divides them into six groups

1 Local syncope of the most simple form
2 Local asphyxia and superficial gangrene with predominance of the nervous element
3 Symmetrical gangrene of the extremities of benign form
4 Symmetrical gangrene of the extremities of grave form
5 Cases of symmetrical gangrene with lesions of the circulatory apparatus, established by autopsy
6 Doubtful cases, those cases which present less and less certainty, nevertheless they are interesting as a group, because they are in a marked degree removed from what occurs in the common cases, and because they may perhaps one day contribute to clear up many obscure points It is not impossible that we may have here a very advanced form of the malady which occupies our attention

Under the latter, he cites a very interesting case reported by Bernard Schrader as follows "In 1829 while traveling with my brother, Jean Schrader, and Alexander Lak, studying surgery, we found ourselves in a town called Giest and having entered a hostelry, the master, who was called Jean Brandes, made us see his daughter, aged 23 years who was attacked with the following malady each month she suffered from severe pains in the extremities of the fingers, and of the toes, accompanied by edematous swelling of the face, feet and hands This was followed by sphacelus or mortification of the extremities of those parts in which the pain was first felt, which became pale, dry, insensitive, nevertheless with no bad smell, and with no humor proceeding from them

"These gangrenous parts separated each month in small morsels, which preserved their normal form While informing me more particularly of the circumstances of this illness, the father of the girl showed me a box in which there were more than a hundred of these morsels of dead flesh which, in the space of three years, had been thrown off and detached from the extremities of different parts of the body of this girl"

As the name implies, the gangrene affects usually symmetrical parts of the body, more frequently the toes of both feet or the fingers of both hands and the two halves of the nose Still there have been cases reported of late, which are undoubtedly of the same etiologic relation, involving asymmetrical parts In the Nov 16, 1893, number of the *Wiener Klinische Wochenschrift*, Docent Riehl reports a case of symmetrical gangrene in a hysterical patient, which could be classified under Raynaud's second division of cases

A similar case is reported in the *Wiener Klinische Wochenschrift* of May 3, 1894, by Ehrl Characterizing both these cases, were well-marked hysterical symptoms, such as localized anesthesia, diminution of the field of vision, achromatopsia, and ovarian tenderness

I am indebted to Dr Anson Brackett, of Nashua, Iowa, for the following history, having seen the patient in consultation with him in the summer of 1891

Miss A E C , American, age 37, occupation that of a seamstress Hair brown, eyes gray, height five feet eight inches, weight about 140 pounds Complexion a little sallow Lips pale, conjunctiva pale, blood vessels of the face ectatic, in spots, giving the skin a blotchy appearance, digestion good, bowels regular, appetite capricious Patient had a severe attack of gastritis when she was 20 years of age, and has never menstruated since Vaginal examination not permitted, but no tenderness or abnormal condition appreciable by external examination Urine normal, sp gr 1020, acid in reaction Lungs and heart normal, as well as the abdominal viscera The patient has never been robust since her sickness seventeen years ago, her health has been fair, has had to work very hard indoors in poorly ventilated quarters and was defrauded of her small savings a few years ago, which still further depressed her, and necessitated a renewal of incessant labor She often sewed late into the night In May, 1890, she began to feel badly No definite symptoms were manifest, but she complained of general malaise over a period of some weeks This was followed by feeling cold, yet with no distinct chills The next manifestation was severe and protracted pain, localized in different spots on both lower extremities The pain was accompanied by a burning sensation in these spots, followed by intense redness, which gradually assumed a purplish hue ultimately turning black, and surrounding each was a well marked line of demarkation These spots, varying in size from that of a split pea to three inches in diameter limited to both thighs, below the middle third, and exquisitely sensitive to touch After the line of demarkation had formed, separation took place very slowly, leaving a dirty gray base, which healed gradually, it being weeks before cicatrization took place There was no elevation of temperature except locally The pulse was rapid, lacking in tonus, becoming quite thready at times The general condition was that of great exhaustion and loss of vitality

The treatment was purely symptomatic, as a tonic, strychnia and iron was given in full doses, rest, nutrition, general attention to hygiene of surroundings Locally, flaxseed meal poultices and iodoform After a few months she was able to get out of doors some, but walked with difficulty and was easily prostrated During the summer of 1893 she had a recurrence of the condition, not so severe, however, the gangrenous spots seeming more superficial, in some of them a partial line of what might be called demarkation formed, followed by bullæ of considerable size which were filled with a serous fluid and which soon dried up These did not in the least resemble those of pemphigus She had exacerbations and remissions of these lesions from time to time since, spending most of her time in bed in a weak and debilitated condition until about six weeks ago, when death relieved her

Post-mortem examination not allowed No tests were made for hematuria or hemoglobinuria, nor were the gangrenous masses examined for chemic agents The urine contained no sugar, nor could any history of ergot or other medicinal poisoning be obtained, of local processes The following could be entirely excluded, such as anthrax, furunculosis, phlegmon, as also gangrene from embolus of the vessels supplying the parts, as well as herpes zoster gangrenosum

Affleck reports two cases of Raynaud's disease, the second of which was such a typical one that it will be well to briefly describe it

A kitchen maid aged 16, entered the hospital, stating that during six months preceding she had been subjected to severe pains in her hands and feet, very severe for eight days before entrance The pains soon subsided in her feet, but became worse in her right hand, the tips of the fingers of which were blanched and corpse-like There was great pain and at the same time anesthesia of the hand The left hand presented the same appearance only in a milder form The toes again became painful, but appeared perfectly normal Physical examination of the patient revealed no pathologic or abnormal condition except that no brachial, radial, nor ulnar pulse could be felt in the right arm The right subclavian and axillary arteries were smaller than the left, and the circumference of the right arm and hand was about one-half an inch smaller than that of the left

The arm was treated by means of warm opium fermentations, after which, whenever these removed, the hand first appeared blanched but very soon became purple and so painful that the fermentations had to be reapplied Three days after entrance to the hospital there appeared in the tip of the middle and ring fingers, a dark spot which eventually sloughed off The patient improved and left the hospital, but no pulsation could at any time be felt in the right arm

In the other case, there was no clear history of the stage of ischemia of the skin, both feet being attacked instead of one hand, and the gangrene was much more extensive, following a Symmes amputation of the left foot, an examination of the nerves revealed a neuritis, and to this might be added numerous other cases, especially those of Pitres and Vaillard, in which the same pathologic changes in the nerves had taken place

The following are the most common themes regarding the etiology and pathology of the disease

1 Endarteritis obliterans
2 Peripheral neuritis
3 That championed by Raynaud, namely, a vascular spasm

Cases included under these various theories have been cited from time to time, some claiming that the peripheral neuritis is only secondary to the vascular disturbances, and others that the neuritis is primary and responsible for the gangrene This latter view is held by Pitres and Vaillard

In support of his theory of spasm of the smaller arteries, as the causative factor in local asphyxia of the extremities, Raynaud reported a case of remarkable coincidence between the peripheral circulatory disturbances and identical phenomena observed with the ophthalmoscope in the retinal circulation which phenomena became manifest clinically by an intermittent obscuration of vision Regarding the treatment, Barlow states that in a great many cases of symmetrical gangrene, amputation is necessary, as in other forms of gangrene, but in those cases where the gangrene is superficial he strongly advises the use of the constant current The extremity of the limb which is the subject of gangrene is immersed in a large basin, containing salt and water, one pole of the battery is placed on the upper portion of the limb, and the other in the basin, thus converting the salt water into an electrode, opening and closing the current repeatedly to get moderate contractions In connection with this method, gentle massage ought also to be tried after the acute pain has subsided

EXHIBITION OF SPECIMENS OF PYOSALPINX,

by *Dr. Weller Van Hook* *I have brought with me this* evening a specimen from a case upon which I operated last Friday It consists of tubes and ovaries which were removed for salpingitis or as Martin calls this condition sactosalpinx purulenta If there is any interesting point about the specimen it is this, that we have here an acute inflammation engrafted upon a chronic inflammation, the tubes and ovaries having been removed during the acute attack The patient was a married woman 28 years of age, with one child 6 years of age Her husband confessed to having had *gonorrhea some twelve years ago, but assured me that the* disease was entirely cured, and the patient does not give a history that she had an acute attack of gonorrhea at any time It was only after the child was born that she had a pelvic inflammation She has since had repeated attacks of salpingitis after which she partially recovered, but had the usual pain and suffering that such women endure She menstruated eight or ten days ago, but on the third day of menstruation the menses suddenly stopped, and she began to have intense pain in the abdomen, with elevation of temperature and other signs of acute salpingitis Two or three days later the tubes were removed Upon examining them it will be seen that they are intensely congested, but that the main portion of their surface is of a yellowish tint In strictly acute salpingitis, either puerperal or gonorrheal the color of the tubes is a vivid red

There are the usual evidences of the tubes having been removed forcibly and the adhesions torn off The fluid in the larger tube is of a straw color, somewhat inclined to be viscid, and is loaded with staphylococci

Martin's new book on the diseases of the tubes, which has just appeared, is a most interesting work and, I am sure, will be read with eagerness by every one interested in this work He presents beautiful chromo-lithographs of such conditions as are shown by these tubes

---

American Public Health Association

Proceedings of the Twenty-Third Annual Meeting held in Denver Colo, Oct 1–4, 1895

FOURTH DAY—FRIDAY OCTOBER 4

(*Concluded from p 676*)

The concluding session of the meeting of the Association was called to order shortly after 9 o'clock by PRESIDENT BAILEY

After various announcements on behalf of the Local Committee of Arrangements had been made by CHAIRMAN SEWALL, the Executive Committee submitted the following recommendations that the Standing Special Committee "On Restriction and Prevention of Tuberculosis," be discontinued Adopted

Three applications for membership were then elected members of the Association in the usual manner This was followed by the report of the Advisory Council which was read by Secretary Grey, and consisted in naming the officers and three members of the Executive Committee for the ensuing year, all of whom were unanimously elected as follows

President, Dr Eduardo Liceaga, of the City of Mexico, Mexico

First Vice-President, Col A A Woodhull, U S A, Denver, Colo

Second Vice-President, Henry Sewall, Denver, Colo

Secretary, Irving A Watson, Concord, N H

Treasurer, Henry D Holton, Brattleboro, Vt

Buffalo, N Y, was named as the place for the next annual meeting

The new members of the Executive Committee are

J C Shrader, Iowa City, Iowa
R S Goodwin, Thomaston, Conn
James F McShane, Baltimore, Md

Regarding the time the next annual meeting should be held, as suggested in the President's address, it was moved and duly seconded that the option be placed in the hands of the incoming President, Vice-Presidents and Secretary, and if they thought it best that the meeting be held in September, 1896, *to arrange for it to be held* during that month instead of October

PRESIDENT BAILEY announced these committees, a number of names being substituted during the reading as occasion required

ADVISORY COUNCIL

Alabama—Jerome Cochran, Mobile
Arkansas—H C Dunnavant, Osceola
Connecticut—R S Goodwin, Thomaston
California—J R Laine, San Francisco
Colorado—W P Munn Denver
Delaware—Mr W C R Colquhoun, Wilmington
Florida—Joseph Y Porter Key West
Georgia—William F Brunner, Savannah
Illinois—Liston H Montgomery, Chicago
Indiana—Lindsay S Whitesides, Franklin
Iowa—A. W Cantwell, Davenport
Kansas—Dr Gifford, Topeka

COMMITTEE ON THE USE OF ALCOHOLIC DRINKS FROM A SANITARY STANDPOINT

Felix Formento, New Orleans, La
C O Probst, Columbus, Ohio
E P Lachapelle, Montreal, P Q

The appointment of the chairman of the Local Committee of Arrangements was referred to the new administration

Mr Crosby Grey offered a motion duly seconded that when the Association adjourns, it do so at 11 45 o'clock The motion prevailed

The following resolution offered by Dr J N McCormack was unanimously adopted

Resolved, That the members of the American Public Health Association desire and hereby tender most cordial thanks to all concerned in inviting and bringing the twenty third annual meeting of the Association to the beautiful Queen City of the Plains, the Committee of Arrangements, the physicians and citizens, the Chamber of Commerce and especially to the ladies of Denver for the attentions and charming hospitalities which have made the stay here a pleasure, to the various railroad companies for reduced rates, to the Brown Palace Hotel for the use of its hall and to the newspapers for reports of proceedings We also express thanks to Dr Cantwell and other citizens of Davenport, Iowa, for courtesies extended at that point, and to the retiring President for the able, courteous and dignified manner in which he has presided over the meeting

Dr Henry Mitchell moved, duly seconded, that a committee of three be appointed by the chair to communicate with the Postmaster General regarding the transmission of bacteriologic specimens through the mails, in accordance with the resolution adopted on Wednesday forenoon by the Association The motion prevailed

At the instance of the Special Committee on National Legislation of the American Pharmaceutical Association, of which Dr F E Stewart of Detroit, Mich, is chairman, Dr Liston H Montgomery submitted letters and a resolution to the new executive committee, looking to the securing of uniform poison laws in all the States, as the laws at present regarding the sale of poison are not in accord For instance a poison can be legally sold as such in most States only with the label of warning, and after registration by a competent pharmacist Put it up in the form of a proprietary medicine, and it is at once beyond the restraint of regulation and then it may be sold by anybody without let or hindrance

REPORTS OF SPECIAL COMMITTEES

Dr Irving A Watson reported for Dr Charles Smart, chairman of the Committee on the Pollution of Water Supplies, that the committee is hard at work and that this be regarded as a report of progress, with the request that the committee be continued, which was so ordered

Dr P H Bryce reported briefly for himself as the chairman of his Committee on International Pollution of Water Supplies, which was on motion referred to the new executive committee

Mr Rudolph Hering, chairman of the committee on the Disposal of Garbage and Refuse, submitted an elaborate report, yet he stated that it was not complete The speaker read but a few moments, when upon motion, the report was accepted, referred to the Publication Committee, and the committee continued in accordance with previous appointment

Reports were due, although none were presented, from the following committees On National Health Legislation, On the Cause and Prevention of Diphtheria, On Causes and Prevention of Infant Mortality, On the Transportation of the Dead

Thirteen papers were announced to be read on the morning's program A few were read with little or no discussion on the propositions evolved The first paper was presented by Dr Eduardo Liceaga of the city of Mexico, entitled,

A CONTRIBUTION TO THE STUDY OF YELLOW FEVER IN CONNECTION WITH ITS MEDICAL GEOGRAPHY AND PROPHYLAXIS IN THE MEXICAN REPUBLIC

The speaker contended that the means of combating the disease must be sought in the inoculation of blood serum from persons already attacked, or rather who have suffered from yellow fever, or by inoculation of blood serum from animals that have acquired immunity Yellow fever does not exist in an endemic condition except in the port of Vera Cruz, and in the northern districts of the peninsula of Yucatan There is not nor has there been a single endemic source of this disease on the Pacific Coast of the Mexican Republic The only epidemic during the present year was that which occurred at Vera Cruz with a mortality of 120, between January and August

The second topic was a paper on

PROPHYLAXIS OF YELLOW FEVER,

by DR MANUEL CARMONA Y VALLE, also of the city of Mexico, which was read in English by Dr Formento, while his colleagues and the author attentively listened The writer said in part By the inoculation of a yellow fever sufferer with his urine the disease is stemmed and finally eradicated from the system In 1882 he began treating victims of the scourge with subcutaneous injections of urine and success followed He discovered that he could vaccinate a sound person with the fluid from a patient who was over four days diseased, and that those undergoing the operation were immuned from any further danger of contagion The injection is made in the cellular tissues of the back part of the arm and from 1,358 inoculations made by him, there has never followed any other consequence than the formation of a single abscess in the place of injection This method has been used by Dr Garcia del Formel in Panama with great success The essayist, while first experimenting, treated 208 persons in 1882–83 Only one out of this number, a relative employed in the custom house in his city became slightly ill, not sufficient for him to go to bed with the malady Continuing he said that Surgeon General Sternberg of the U S Army, who had been *in correspondence with him, proposed* that the residuum of urine be obtained by the evaporation of the liquid in a vacuum M Bouchard of Paris, had been for some time investigating the author's method of treatment, with successful results in the case of inoculated animals The Doctor recommended to his colleagues in the United States that they use the residuum retained in small flasks which should be perfectly aseptic and hermetically sealed, when treating a case of yellow *fever His own method before making an inoculation* is to dissolve 5 centigrams of residuum in 1 gram of pure water, then inject with a Pravaz syringe

In the brief discussion that ensued Dr Woodhull expressed his thanks to both writers and the authors of the foregoing papers for their contributions on yellow fever, and particularly for the last one The reading of that paper was to him exceedingly interesting as he thought it was to all the gentlemen present

DR FORMENTO—said that there is a great future in the study of the prophylaxis of this disease Since 1880, yellow fever has, been kept out of New Orleans as all cases are quarantined at the quarantine station in the river below the city He had no doubt that the substance found in the urine of patients suffering from yellow fever will produce immunity from the disease to others if they permit themselves to be inoculated in the manner described by Dr Carmona y Valle

A paper was delivered in Spanish by DR JESUS E MONJARAS of San Luis Potosi, Mex, "On the Necessity for the Establishment of Sanatoria to Prevent Chlorosis as the best Prophylactic against Consumption in Particular, and Constitutional Diseases in General," upon which there was no discussion He was followed by DR GREGORIO MENDIZABAL of Orizaba, Vera Cruz, Mex, who read a paper

ON BATHS, THEIR NECESSITY, THEIR INFLUENCE IN ECONOMY, THE DANGERS THEY PRESENT, AND THE METHODS OF PREVENTING THEM,

of which these excerpts were taken cleanliness is without dispute, the fountain of beauty, as it is also the most pure spring of human health The writer referred to the fact that cleanliness is a preventive of disease The importance given to bathing by the Egyptians Persians, Greeks, and above all the Romans was considered The first act of Eastern hospitality during the remote ages, consisted in offering a bath to the traveler seeking the shelter of a roof The gigantic Roman ruins, and the degree of prominence given to ablution in that exalted nation whose legions triumphantly traversed the greater part of the then known world was dwelt upon Unfortunately civilization, the corruption of morals, as John Jacob Rousseau says converted in an evil day those fountains open to all as well to the high born as the plebeian, the rich as the poor, the wise as the ignorant, and from which those people obtained such benefits to health and virility—into amphitheaters of corruption and iniquity, into centers of depravity and effeminacy, making them abominable in the eyes of men of pure heart and habits who succeeded the villified race of that abject Roman Empire These institutions having gone out of use, it was necessary to go slowly again over the same ground and provide the social classes with the most easy and economical means of cleansing their bodies and clothing, as well as to preserve them from the thousands of ailments emenating from negligence and ignorance

This is one of the *many*, and perhaps most interesting propositions of contemporary hygiene, and the boards of health have *not* been idle, *and their gospel* has begun to bear fruit We note with satisfaction the rivalry between modern cities in procuring for each inhabitant the greatest possible number of gallons of water, and supplying it so cheaply as to place the means of cleansing within the reach of even the most destitute of our race The advantages of hygiene were further proclaimed to show that the indifferent and indolent poor would be benefited by a strict observance of it The physiologic and therapeutic properties *of cold water were noted*, how it raises the standard of health, invigorates the most debilitated constitutions, and assuages nervous excitement, etc The shower bath is a good tonic because it gives rise to a *healthy perspiration* It does not irritate and one is less exposed to a cold than in a tub because the duration is very *short* the body *is more thoroughly* cleansed as all impurities are removed *from* the skin by the continually new and pure falling water It satisfies *also the demands of economy* without any extra expenditure of water

Public baths have reached the highest state of perfection in Germany, Austria and England, and these countries have produced in the last fifteen years the largest number of scientific works on the subject

The city of Berlin shows with pride to travelers her bathing department in the barracks of the Grenadier Guards wherein 300 soldiers can bathe themselves hourly, each consuming only from 10 to 15 liters of water

The City of Mexico which had hitherto *only a supply of from 65 to 70 liters* of water per *inhabitant, will* double this allowance within a short time and will augment the number of modern bathing centers where prices will be arranged within the reach of all

The government is now constructing a bathhouse in Lagunillas Square, applying to the object a private donation, in which the poor will find hot and cold shower baths, with the further privilege of having their soiled linen washed while they are on the premises

The speaker then dwelt upon the manner in which diseases may be contracted in badly kept and imperfectly cleansed tubs, through the use of sheets *towels*, combs, brushes, etc, he recited the various kinds of disease that had come under his observation contracted in this manner and concluded by saying, the necessity of having public baths kept absolutey clean is imperative, otherwise they act as disease disseminators

An abstract of a paper on

SMALLPOX IN WISCONSIN FROM JANUARY 1894, TO JUNE, 1895,

was presented by DR U O B WINGATE, *of* Milwaukee, Wis

The State of Wisconsin has an average length of about 260 miles, breadth 215 miles, and an area of 56,000 square miles, or 35 840,000 square acres In other words, its territory is nearly equal to that of England and Wales together The highest elevations are about eighteen hundred feet above the level of the sea, and the lowest six hundred feet It is divided into seventy counties, and has a population, according to the census of 1895, of nearly 2,000,000 It has one city of about 250,000 population, and a total of 1,235 cities, villages and towns, out of which number there are 48 cities with a population ranging from 25,000 to 40 000 respectively Each city, village and township is required by law to have an organized local board of health, consisting of a chairman, a secretary and a health officer, who is the executive officer of the board There are a few townships in the sparsely populated districts that have not conformed to the requirements of the law There are, however, about 475 legall organized local boards of health in the State

Prior to 1894, smallpox had not existed in the State for a number of years with the exception of now and then a sporadic case At the beginning of 1894 the disease showed an alarming increase in the city of Chicago, Ill During January of that year three cases occurred in the interior of this State and one in the city of Milwaukee The disease did not seem to spread from these cases, but soon after it began to appear in different places throughout the State In some instances it could be traced directly to Chicago The State Board of Health adopted its vaccination rule which required that no child could be admitted to school without presenting a certificate of successful vaccination This rule was of general application throughout the State It also urged vaccination of all teachers, inmates and employes of all institutions, factories, etc There was, however, a very active anti-vaccination society at work in the city of Milwaukee, and its influence spread more or less over certain portions of the State, but subsequent reports showed that the rule was very generally observed, and especially in those localities where the disease made its appearance

The disease increased and reached its height in the State about the middle of October, 1894, when it began to decline and entirely disappeared in the month of June, 1895 It appeared in thirty-one out of the seventy counties, and in fifty-eight places A table showing the number of cases in each county, and number of deaths was then given Out of the total number of 1,412 cases throughout the State, with 352 deaths, 1,197 cases occurred in the county and city of Milwaukee, with 299 deaths

The total death rate in the State was 24 92 per cent, while in the city of Milwaukee there were 1,060 cases with 271 deaths or 25 56 per cent Out of this number 575 cases were treated in the hospital with 134 deaths, giving a death rate of 22 53 per cent Four hundred and eighty-five cases were treated in houses, with 137 deaths, giving a death rate of 28 25 per cent Out of the 1,060 cases, a history of vaccination was obtained in 1,016, 343 of which gave a history or presented evidence of vaccination some time prior to the attack Of this number, 35 died, or 10 21 per cent Six hundred and seventy-three cases gave a history of having never been vaccinated Of this number 191 died, or 28 38 per cent

In several instances the disease was promptly stamped out If a second focus of infection was introduced some weeks or months subsequently, again it would be promptly stamped out

In the majority of instances, public sentiment sustained the State laws, which are ample and sufficient, if properly enforced, to control an outbreak of contagious disease of any kind in Wisconsin Although great difficulty was at first encountered in the city of Milwaukee, for a time, to overcome the prejudice of a certain class who did not appreciate the value of sanitary law and its enforcement, riotous demonstrations occurred which are already a matter of history

Vaccination to be effective must be repeated sufficiently often to keep the system immuned from the disease, and until that time comes there will be smallpox Until every person will take it upon himself to be re-vaccinated every four years, on the same principle that he would have a fire or life insurance policy renewed when it runs out, we can never expect to be absolutely protected from smallpox Some persons vaccinated in infancy may remain immune for a lifetime, while with others immunity will last only a few years The only safety is in oft-repeated vaccinations, Pure certainly as often as every five years lymph should be propagated absolutely under the control of the State or National government, and should be taken out Until this of the hands of commercial interests is done it is no wonder that the people, or quite a proportion of them, oppose vaccination on the ground of impure and The writer believes this is unreliable vaccine true also of the antitoxins and similar products used for immunizing purposes Successful vaccination with pure effective vaccine, and isolation of cases, are the two great weapons upon which we must rely to control outbreaks of smallpox, and to carry these two means into effect we must have both law and education

The death rate, as shown by all statistics with which the author is acquainted, show that cases treated in properly constructed and properly managed isolation hospitals is decidedly less than of those cases treated in homes In the great majority of instances, in cities especially, cases of smallpox can not be properly isolated at home without People should be taught danger to the public the advantages, not only to themselves but to their neighbors, of being removed to isolation hospitals for treatment Another great work to be done, is to educate communities up to the importance of appropriating a sufficient amount of money to erect and maintain in every city suitable hospitals which should be in every way so well equipped that no complaint can be brought against them, and which should be maintained at public expense, that the comforts enjoyed therein by patients ill with contagious diseases are equal to or greater than those enjoyed in the majority of homes By such provisions, epidemics of smallpox can be easily controlled, and not only life and health saved, but the enormous expense to every community which necessarily occurs in which any extended outbreak of this disease exists

President-elect Liceaga was then escorted to the chair by Drs Formento and Horlbeck and formally inducted into office

Senors —I consider the honor bestowed upon me as an honor to my country, and I thank the Association I consider that among my own countrymen present, there are men more worthy of the honor, and on that account I feel a personal debt of gratitude to the Association I can assure the Association that my deficiencies will be compensated by devoting all my intelligence, good will and energy to become worthy of the great honor conferred upon me

President Bailey the retiring executive officer, thanked the Association for courtesies shown him, and assured his friends that the occasion would be one of the delights of his lifetime He then adjourned the Association at 11 35 o'clock to reconvene at the Antlers Hotel, Colorado Springs on Monday morning at 10 o'clock October 7

Colorado Springs, Colo, Monday, October 7 —About one hundred members of the American Public Health Association visited this city last Saturday and remained over until to-day The citizens and medical profession of Colorado Springs and Manitou entertained the Association in a luncheon at Broadmoor Casino and in a trip to Cheyenne canon and other points of interest in the Pike's Peak region, including a drive through Glen Aerie, the Garden of the Gods, etc, this program was carried out to the letter The remaining visiting members passed a resolution of thanks for the numerous courtesies and hospitalities they received during their brief sojourn in this beautiful city, after which the Association adjourned *sine die*

Some arrangements had been made to start from the Union depot in Denver on Friday afternoon after adjournment, for a trip around the famous "Georgetown loop" to Silver Plume This included a "stop over" at Idaho Springs, but the inclement weather then prevailing made the undertaking too hazardous and it was therefore abandoned

Thursday afternoon the 3d inst, the members with their families and invited guests indulged in a trolley ride about the city and suburbs which included about forty-five miles, starting from the headquarters at 2 o'clock This was tendered by the Denver Chamber of Commerce The ride included a visit to the Zoological Gardens at the outskirts of the city Many members also availed themselves of the invitation extended by Col and Mrs A A Woodhull, to an afternoon tea where the genial host and hostess entertained the visitors at their hospitable home, 1020 Logan Avenue, on Wednesday the 2d inst, the lady delegates and visitors were invited to an afternoon tea given by Mrs N P Hill at her residence, corner of Fourteenth and Welton Streets This proved to be a most enjoyable and delightful affair During the evening, a reception for the members and their friends was given in the parlors of the Brown Palace Hotel The De Harport orchestra was in attendance, and the care with which the details of the reception were carried out made it a perfect success It was stated that there were upward of 400 ladies and gentlemen present during the evening The parlors were beautifully embellished for the occasion It was while this was in progress shortly after 9 o'clock that the Mexican delegation arrived which altogether included fourteen members During the day also at various intervals, the program was varied by a visit to the Denver Athletic Club and to the Smelters, in a tally ho which was furnished by the Local Committee of Arrangements

Tuesday evening, the 1st inst, after the open public meeting in Trinity M E Church, the program was of a semi-social and semi formal character His Honor the Mayor, and Mrs T S McMurray, Dr and Mrs J H Gower, Dr and Mrs Henry Sewall, Dr and Mrs J N Hall introduced the guests to the citizens

Monday afternoon the 30th, at 1 30 o'clock the members and their friends were invited by the Denver Union Water Co, to inspect the water works of the mountain supply in the Platte canon, twenty two miles from Denver Special cars were provided for the occasion, also dainty refreshments However pleased the Association might have been with the source of Denver's water supply for drinking and domestic purposes it did not formally indorse it

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE INCLUDING POSTAGE
PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO 86 FIFTH AVENUE CHICAGO ILLINOIS
W H LOWDERMILK & CO WASHINGTON AGENT

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, Venetian Building, Chicago, Ill , sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago

SATURDAY, OCTOBER 26, 1895

CONCERNING PORTRAITS

Animum pictura pascit inani —VIRGIL
And with the shadowy picture feeds his mind '

We have had many letters from members of the ASSOCIATION making inquiry about the probable disposition of the photographs of the members, which this JOURNAL has been receiving from time to time for the last six months

Some other journals have even been facetious when mentioning the matter The truth is that few things are of more interest historically than the pictures of the men who make the history, and from the earliest times it has been a common complaint that the world was indifferent to contemporary portraits

PLINY ("Natural History") lamented that his age possessed no portraits of living men "Correct portraits of individuals," says PLINY, "were formerly transmitted to future ages by painting, but this has now fallen into desuetude Brazen shields are now set up, and silver faces with only some obscure traces of the countenance, the very heads, too, of the statues are changed, a thing that has given rise before now to many a current sarcastic line, so true it is that people prefer showing off the valuable material to having a faithful likeness And yet, at the same time, we tapestry the walls of our galleries with old pictures, and we prize the portraits of strangers, while as to those made in honor of ourselves, we esteem them only for the value of the material, for some heir to break up and melt, and so forestall the noose and slipknot of the thief Thus it is that we possess the portraits of no living individuals, and leave behind us the pictures of our wealth, not of our persons And yet the very same persons adorn the palæstra and the anointing room with portraits of athletes and both hang up in their chamber and carry about them a likeness of EPICURUS "

PLINY referred with pleasure to the practice of his ancestors, so entirely different Family portraits were arranged each in its separate niche, to be always in readiness to accompany the funeral processions of the family, occasions on which, by this practice, every member of the family that had ever existed was always present

"Indeed," says PLINY, in concluding his interesting chapter on portraits, "it is my opinion that nothing can be a greater proof of having achieved success in life, than a lasting desire on the part of one's fellow men to know what one's features were This practice of grouping portraits was first introduced at Rome by ASINIUS POLLIO " It was VARRO who first inserted portraits in books

"What," says the elder D'ISRAELI[1], "is more agreeable to the curiosity of the mind and eye than the portraits of great characters? An old philosopher whom MARVILLE invited to see a collection of landscapes by a celebrated artist replied, 'Landscapes I prefer seeing in the country itself, but I am fond of contemplating the pictures of illustrious men ' This opinion has some truth, LORD ORFORD preferred an interesting portrait to either landscape or historical painting 'A landscape,' said he, 'however excellent in its distributions of wood and water and buildings, leaves not one trace in the memory, historical painting is perpetually false in a variety of ways, in the costume, the grouping, the portraits, and is nothing more than fabulous painting, but a real portrait is truth itself and calls up so many collateral ideas as to fill an intelligent mind more than any other species ' "

It is a false pride which refuses to have a picture taken "Do you not think," said DASSIER, the painter, to MONTESQUIEU, "that there is as much pride in refusing my offer as in accepting it?"

The voice of antiquity, not less than that of modern curiosity, urges us to make these collections of our contemporaries while we can, and before TIME, that subtle painter, shall have changed all the lineaments that made the physiognomy characteristic of our friends in the active period of their labor

ADDISON, who placed the line from VIRGIL which we quote at the head of this article, at the beginning of his charming vision of a picture gallery, observed "an old man creeping up and down from one picture to another, and retouching all the fine pieces that stood before me I could not but be attentive to all his motions I found his pencil was so very light that it worked imperceptibly, and after a thousand touches, scarce produced any visible effect in the pictures on which he was employed However, as he busied himself incessantly, and repeated touch after touch without rest or intermission, he wore off incessantly every disagreeable gloss that hung upon a figure He also added such a beautiful brown to the shades and mellowness to the colors, that he made every picture more perfect than when it came fresh from the master's pencil I could not forbear looking upon the face of this ancient workman, and immediately by the long lock of hair on his forehead discovered him to be TIME " And so, while TIME may produce the "wrinkled front," he blends the wrinkles deftly, until the face most worthy of protracted study is that of the sage, mellow with age and accumulated wisdom

---

[1] Curiosities of Literature

Let then, our old and young members alike aid in furnishing our portrait gallery with their pictures They will be deposited in the ASSOCIATION Library, as among the most sacred archives of our noble ASSOCIATION What would our generation give for an authentic portrait of HIPPOCRATES or GALEN, or of the medical masters of medieval times, and yet our time will some day be quite as remote from distant posterity Opportunity may indeed prevent this age from producing a counterpart of HIPPOCRATES or GALEN, but measured by the sum total of the reduction of human suffering, the age that produced anesthesia can never be uninteresting or unimportant

THE COLOR SENSE AND RAILWAY AND SEA SIGNALS

The importance of systematic examination of the color sense in seamen and railway employes is now so thoroughly recognized that it is perhaps commonly thought that all the requirements for the safety of life and property are met by the system now in vogue The complete weeding out of all who show defects of color vision from these employments is the ideal of the ophthalmologists and of those who have made a specialty of this subject, like DR JEFFRIES, of Boston, and some others Against them, however, there is sometimes raised a voice, for example, DRS DIBBLE and OUTTEN at the last meeting of the Association of Railway Surgeons, and MR F FERGUS, in a recent issue of the *Glasgow Medical Journal* These objectors assert that there are cases that are rejected by the usual tests that are perfectly competent to meet all practical emergencies, and that any rigid tests apart from those directly practical sometimes work injustice It is asserted also by some, that considering the fact that 4 per cent of males are more or less defective in their color vision, there ought to be a larger proportion of accidents by land and water directly traceable to these defects during the many years that these defective individuals have been employed

DR W R GOWERS, in a communication in the *Lancet*, last March, asked for direct evidences of accidents due to this cause, the replies he received were surprisingly few in number, and the instances given were in part those mentioned by JEFFRIES, which are, so to speak, the classic ones in the literature

Recognizing however, as one must, the difficulties of establishing all the causes of accidents by rail or sea, it may be admitted on *a priori* grounds that the element of defective color vision is an important one among the possibilities of danger, and that it should be adequately guarded against The examinations can be made sufficiently practical and, where actual hardship results especial care should be taken and some compensation afforded if justice demands it There is more danger probably in the defects of those who can pass the examination successfully than in the chance of a case of imperfect color vision passing it, or in the possible laxity of the tests

The dangers from color blindness are not confined to those who reveal it in sorting worsteds or even to the spectroscopic tests It is a temporary symptom of many possible pathologic conditions, alcoholism, hysteria, tobacco saturation, it may be a relic of acute disease, convalescence from which seems to be complete, and lastly it may probably be sometimes the direct temporary result of mental stress, so that in certain emergencies where it is most needed it may be wanting These cases are the more dangerous in that they are unsuspected, and caution and suspicion are done away with by the successful result of the prior examination To trust human life implicitly and solely to the perfection of so delicate and easily deranged a function, when additional precautions for safety are practicable and readily available, would seem to be almost criminal when all these facts are taken into consideration

Color blindness in these cases, as well as probably in many congenital ones, as was maintained nearly fifteen years ago by BANNISTER and BURNETT, is probably a psychic rather than a retinal disorder, and this psychic factor is a possibility to be always considered The danger, therefore, is that we shall depend too much upon a refinement of a sensory function that is defective in an appreciable percentage and may possibly fail under critical circumstances in a much larger proportion

The advisability of supplementing the color signals by some other and more efficient device has long been recognized by practical navigators, and it is efficiently done upon the inland waters of the United States by the use of range lights on steamers, which has lately been made compulsory also on the lakes They have the advantage over the colored lights, of greater range of visibility, of being distinguishable at all times, and of affording data by which to ascertain the exact course of the approaching steamer Whether any analogous arrangement is equally available in railway practice is perhaps a question, but there can be no doubt that a semaphore arrangement of lights for a danger signal would always be a most useful addition to the colored lights now employed

The subject has important medical as well as practical bearings, and it would be well were it fully discussed in the medical press

UREMIC PERICARDITIS

The frequency of pericarditis in chronic nephritis is well known BUHL (*Mittheilungen a o pathol Institut München*, 1878) estimated the frequency at 35 per cent of the observed cases, BAMBERGER, (*Volkmann's Sammlung klin vortrage*, 1878, No 173) at 14 per cent and WAGNER (*Ziemssen's Encyclopedia*, 1882) observed pericarditis fourteen times in 150 cases of chronic nephritis Many of the earlier writers believed the cause of this inflammation of the pericardium, as well as of other tissues, in the course of chronic nephritis, to be toxic substances circulating in the blood which the kidneys failed to eliminate Under the influence of the study of bacteriology the opinion gained ground that pericarditis in connection with nephritis must be due to an accidental infection, and this was the view expressed by LECORCHÉ and TALAMON in their treatise of albuminuria and Bright's disease published in 1888

It is self-evident that in order to determine the exact cause of the pericarditis in a given case, resort must be had to the modern microscopic and bacteriologic examination of fresh material as soon after death as possible There are already a few records published of the examination of such cases and especially by BANTI of Florence He described a case of pericarditis in a uremic in 1888 (*Deutsche med Wochenschrift*, No 44, 1888) in which the exudate and the tissue of the pericardium seemed absolutely free from bacteria as far as could be determined by microscopic examination, by culture experiments and by inoculation into animals BAUMGARTEN (*Baumgarten's Jahresbericht*, Bd IV) was inclined to think that the inflammation in this case was due to microorganisms that had died before the material was examined, but BANTI was not inclined to accept this criticism because the pericarditis had existed only seven days before death Last year (*Centralblatt für Allg Path u Path Anat*, Bd V, No 11) BANTI described a new case of pericarditis in uremia due to arterio-sclerotic interstitial nephritis, in which the exudate and the tissue of the pericardium were found free from microbes after the most thorough examination according to the best methods Aërobic and anaerobic culture experiments were made with large masses of the exudate upon a variety of media, but all remained sterile In this case the clinical manifestations pointed to the existence of the pericarditis for about four days before death

BANTI consequently concluded that in the light of the results obtained from the study of these two cases, the pericardial inflammation was due to toxic substances circulating in the blood in consequence of failure of elimination through the diseased kidneys He then made some animal experiments and found that rabbits in which the pericardium had been cauterized, developed a more marked fibrinous pericarditis after nephrectomy or ligation of the ureters, than animals in whom the cauterization of the pericardium only was made, and which were killed after the same length of time in which the uremic animals died While these experiments were not conclusive, yet they seem to support the theory of uremic pericarditis

In October, 1894, BECO (*Centralblatt für Allg Path u Path Anat*, Bd V, No 19) describes a germ-free case of sero-fibrinous pericarditis in a chronic nephritic, which he is inclined to interpret as due to toxic substances produced by the bacillus coli communis which was present in the blood and in the spleen This view is supported by certain experiments of CHARRIN (*Sem Medicale*, 1894, No 42, p 337) which seem to show that the bacterial toxins may cause serositis without the immediate presence of the corresponding microorganisms In March, 1895, (*Centralblatt für Allg Path u Path Anat*, Bd VI, No 5) BANTI describes two additional cases of uremic pericarditis in which there were no bacteria either in the pericardium, in the blood or in the spleen, and he concludes that the presence of the bacillus coli communis that BECO found in his case was accidental and due to agonal or post-mortem invasion

From these interesting observations it does not seem unreasonable to believe that there may be a "toxic inflammation" independent of all direct bacterial influence Such observations as BANTI's and others, indicate the necessity of a thorough bacteriologic examination of all cases of pericarditis and other serositis in connection with kidney lesions in general The results obtained are in full harmony with the views concerning auto-intoxication that are rapidly gaining credence at the present time

INADEQUACIES OF ARBITRARY MILK STANDARDS IN ENGLAND—THE "APPEAL TO THE COW"

MR RICHARD BANNISTER, one of the best known officers of the Local Government Board of Great Britain, recently occupied the chair as President of the Section on Chemistry and Climatology of the Congress at Hull of the British Institute of Public Health His presidential address treated chiefly of the work being done by the governmental bodies for the restriction of food products adulteration He regards the laws as amply framed for the protection of any community, and those communities are blameworthy that refuse to act thereunder Adulteration is sometimes alleged, especiallly in respect to imported foods, when it does not exist The existing laws have already effected an incalculable amount of good, notwithstanding the lukewarm support given them

At this point in his address, according to the *Sanitary Record*, he turned his attention to the all-important subject of the milk supply, a subject which he held was attended by many more difficulties than is commonly admitted He presented facts and figures going to show the great necessity to study the milk and butter question in all its bearings, and to see what difficulties there were in the way of carrying out this part of the analyst's duty with justice alike to himself, the producer, and consumer With regard to milk, many difficulties would be removed if the statement made by an expert to the Parliamentary Committee on Adulteration in 1894 were true, that the quantity of fat varied in milk, but the other constituents were wonderfully constant, and they hardly varied at all, and that according to certain rules he could tell how much water had been added to a given sample of milk, or how much cream had been taken from a given sample of milk This unfortunately is not the case Government officers have publicly declared that it would not be in accordance with the design of the Act that a poor man should be subjected to penal proceedings because his cow does not produce as good milk as the better herds of his richer neighbors It has been suggested that a legal standard for milk should be adopted, and that this standard should be the average composition of commercial milk

The hardship of such a standard would be felt by persons keeping a few cows or a single cow in country places, but in the case of town supplies the large distributor would be able to lower this standard by the help of separated milk Again, another point arose, calling for settlement Cows supplying milk under contract were kept as simple milk-producing machines, kept up and fed in such a way as to produce the maximum quantity of milk of the contract quality Was milk so produced, though richer in fat and "solids not fat," as wholesome as that produced by the cow when living under normal conditions? In other words, was the percentage of "solids not fat," and fat, the true standard of value of cow's milk when taken as an article of food? This standard had been taken because it required no question to be asked or inquiries to be made as to the origin of the milk under examination, but in the case of direct milk supply to the consumer by the producer this standard needs to be modified, and in fact, it had been modified, by the magistrates The raising of the standard would not secure the purity of the milk The large distributors would be able to make larger profits than they do now, and the small producer would be more frequently prosecuted for adulteration through no fault of his own In Manchester and Salford the sale of adulterated milk appeared to have been reduced to a minimum, the percentage of adulteration in Manchester being 5 4, and in Salford 3 1 This had been brought about by *appealing to the cows* supplying the suspected milk whenever such an appeal could be made The plan was an expensive one at first, but it eventually paid, and caused the *minimum of hardship to producer*, distributor, and consumer In conclusion, the author of the address said

"Much of the evidence which had been given with reference to mixtures was only a repetition of what was said twenty years ago, before the 1874 Commission, but it had been strongly shown that the trade labored under great hardships from the following causes 1, the non-acceptance by magistrates trying adulteration cases of the certificate of the analytic chemist employed by the defendant, which necessitated his appearance in person at considerable expense; 2, the refusal of the magistrates to allow the defendant his full costs when the case was decided in his favor, and 3, the refusal of some magistrates to allow an appeal to the referees under the Act, and of not accepting the certificates of referees as evidence in the case In all such cases justice must be blind, no prejudice must be imparted into the proceedings on one side or the other, and as the proceedings under the Adulteration Act were criminal, it was their duty to lean to the side of mercy and only proceed when the case was free from doubt The large majority of manufacturers and tradesmen of this country were desirous of suppressing adulteration, and were ready to cooperate with the authorities in so doing It would, therefore, be a misfortune if by harsh measures they lost the sympathy and support of the right-minded, who were willing to aid them in their great movement of protecting the food supply of the nation from adulteration, or of creating an impression in the minds of the Legislature that the legitimate trade of this country was being fettered and injured by their action "

None of the foregoing conditions apply in this country to any extent, and our chemists have a more elastic scale of allowance for the fat percentage There is only one reason why milk dealers are prosecuted in the United States, that is for adulteration, and the fat percentage is only taken into account in our analyses when it falls so low as to show that water has been added The "trade" in this country, have no reasonable complaint, and what the public wants and will have, if it can get it, is pure milk

MEDICAL EXAMINER'S FEES

Elsewhere we print a letter from a correspondent who invites attention to recent action of certain life insurance companies, whereby the fees of the medical examiners are to be reduced This reduction is based on the amount of insurance applied for It is inconceivable that the companies suppose that an examination can be any *different in one case than in* another All cases require the same care and skill, and the same amount of the examiner's time The amount of money involved in the risk is of absolutely no consequence to the examiner, however much the company may be interested, and we think so unjust a plan should be promptly receded from

The majority of examiners are already underpaid, as some of the companies only allow a pittance for an examination requiring not only a great deal of technical knowledge, but the exercise of the highest quality of skilled service, and ability as a cross-examiner

CORRESPONDENCE

A Convenient Test for Color Blindness

La Fayette, Ind , Oct 14, 1895

To the Editor —Being called upon frequently to make color tests for railroad employes, I have been using a method which Dr Carrow of Ann Arbor gave us in a course on ophthalmology Whether it has been published or not, I can not say If it has, this will emphasize its importance and convenience, and if not, will describe it for the first time The skeins of wool have been abandoned as consuming too much time and occupying too much space

The test consists of a sample card of Corticelli embroidery silk On the folding card are 269 colors all named Over the names must be pasted blank paper to hide them These colors may now be numbered consecutively In testing, we direct the patient's attention to one of the colors , blue, green or red We will take, for example, blue, and ask *him* if he sees any color in the green or red column of colors to correspond If he says, no, we point out to him the red, and ask him if there is anything in the blue or green column to correspond If he answers, no, we may then ask him *to name* and point out the colors we have been comparing If he answers correctly, he is not color blind to these colors so important in railway service He must not be told the name of any color He must tell the examiner correctly

On the other hand, however suppose we point out to him a simple blue and ask him if there is any color on the card to correspond and he says there is, and points to green, for example, we know him to be blind to either blue or green To which one, is easily ascertained by asking him the name of the color to which we directed his attention first If he calls the blue color, green, we know that he is blind to blue and *vice versa* If he should say the red is like the blue, we know him then to be color blind to either red or blue To find out which, we need only ask him to name the colors If he calls red, blue, we then know him to be blind to red and *vice versa* If red and green correspond in color to him, his color blindness will be ascertained as above The rest of the card may be used to ascertain the different shades of different colors to which the applicant may be blind

Geo F Keiper, M D

Life Insurance Companies Reduce Fees

La Fayette, Ind , Oct 18, 1895

To the Editor — Both the Equitable and the New York Life Insurance Companies have lately adopted the graded scale of fees to local medical examiners, thus

For three thousand dollars or less of insurance	$3
For from three to twenty-five thousand	5

To be brief and plain, I inclose the blank just received from the New York Life Insurance Company, it explains itself

By the examination of the books of one of our oldest and most reliable life insurance agents in La Fayette, I find that nine out of ten applications for policies are for a less sum than $3,000 insurance showing that this graded scale of fees means a cut of about 40 per cent from old and established rates I do not believe that the doctors throughout the country appreciate this, and I wish most earnestly that you would write one of your instructive editorials on this subject to appear in the Journal at an early day The Equitable circular announcing a reduction of fees is similar to this , in fact, it is my remembrance that it is the same

With best wishes for the Journal and its editor, officially and personally, I am, dear Doctor,

Very truly yours W W Vinnedge, M.D

PUBLIC HEALTH

Antistreptococcin —The *New Remedies*, September, gives a brief reference, from its foreign correspondence, to a new remedial serum bearing the name in the caption It is the latest of the antitoxic serums It has been developed and brought into the therapeutic field by Professor Marmorek "It is said to destroy the pathogenic streptococcus absolutely, and will therefore prove of inestimable value in conditions which are now usually abandoned as hopeless The serum is injected in routine style and does not produce side or after effects" Marmorek is conducting clinical experiments which will be published as rapidly as consistent with reliability Early reports thereon have been promised

A Health Officer Vindicated —The Bulletin for September of the North Carolina Board of Health gives notice that Dr John L Ray, of Burnsville, the Health Superintendent of Yancey County, has received a handsome vindication from certain accusations against him that had found their way into the Public Documents of the State Typhoid fever occurred in the county jail which was in an unsanitary condition There were five cases reported as originating there, and from them not less than twenty-four cases were developed among the townspeople Dr Ray used due diligence in reporting the cases, in applying disinfectants, and in urging the cleansing of the jail by the officers having charge of that institution Notwithstanding his courageous efforts, the Public Documents contained a severe criticism, alleging neglect of duty This criticism, when sifted, was found to be based in part upon a forged report by a clerk of the court The vindication of Dr Ray is found in a numerously signed certificate as to the qualifications and energy of the Superintendent, and as to the falsity of the allegations published in the Documents Among the signers of the certificate are the physicians of the town, or nearly all of them, the mayor, the postmaster, the Representative, the marshal, an alderman, a justice and a score of lawyers and merchants It appears from the Bulletin, that a betterment of the condition of the jail has been effected, following upon the appointment of a new jailer, together with a reduction of the dangers to the community from typhoid fever The Bulletin congratulated Dr Ray on the fact that his courage and efficiency have been vindicated beyond question by a host of competent witnesses

Health Reports.—The following health reports have been received at the office of the Supervising Surgeon-General, Marine-Hospital Service

SMALLPOX—UNITED STATES

New Orleans October 5 to 12, 2 cases, 2 deaths
Michigan Battle Creek Twp , October 5 to 12, smallpox reported , Detroit, October 5 to 12, smallpox reported
Wheeling July 1 to September 30, 3 deaths
Tennessee Shelby County, September 15 to October 15, 3 cases , Memphis, September 15 to October 15, 4 cases

SMALLPOX—FOREIGN

Antwerp September 21 to 28, 1 death
Cairo September 9 to 16, 2 deaths
Calcutta August 31 to September 7, 2 deaths
Corunna July 1 to September 30, 1 death
Dublin September 21 to 28, 18 cases, 2 deaths , Dublin, September 28 to October 5 11 cases, 1 death
London September 21 to 28, 234 cases, 2 deaths , London, September 28 to October 5, 1 death
Madrid September 24 to October 1, 1 death
Manchester September 21 to 28, 4 cases
Montevideo August 31 to September 14, 2 cases, 1 death
Naples September 28 to October 5, 1 case, 1 death
Odessa September 21 to 28, 1 case
Prague September 21 to 28 2 cases
Rio de Janeiro September 7 to 21, 135 deaths
Rotterdam September 28 to October 5, 2 deaths
St Petersburg September 14 to 28, 10 cases, 1 death
Southampton September 28 to October 5, 1 case
Trieste September 21 to 28, 2 cases

CHOLERA

Calcutta August 31 to September 7, 6 deaths
Cognac September 29 to October 5, 1 death
Madras, August 31 to September 6, 6 deaths
Osaka and Hiogo, September 7 to 21, 99 cases, 77 deaths
Tangier September 1 to 30, 800 cases, 600 deaths
Honolulu August 18 to September 28, 87 cases, 62 deaths
Damietta October 15, 15 cases, 8 deaths
Japan fifty cities and towns September 13 to 19, 3,336 cases, 2,080 deaths
From beginning of epidemic to September 19, 46,009 cases, 31,198 deaths

YELLOW FEVER

Cienfuegos, September 6 to 13, 2 deaths, Cienfuegos, September 30 to October 6, 4 deaths
Rio de Janeiro September 7 to 21, 6 deaths
Sagua la Grande September 28 to October 12, 30 cases
St Johns, Antigua September 23 to 30, 3 cases, 3 deaths
Santiago de Cuba September 28 to October 12, 19 deaths

NECROLOGY.

Surgeon-General Sir Thomas Longmore, C B—We regret to announce the death of Surgeon-General Sir Thomas Longmore, C B, which occurred Sept 30, 1895 He was born in London, Oct 10, 1816 His father was a surgeon in the Royal Navy He was educated at Merchant Taylors School In due course of time he became a student at Guy's Hospital He was dresser to Mr Bransby Cooper, assisted that surgeon in his private practice and in writing the life of Sir Astley Cooper He arranged and catalogued the museum of that great surgeon, afterward purchased by the Royal College of Surgeons of England He became M R C S Eng, 1841, and F R C S, 1856, and Fellow of the Royal Medical and Chirurgical Society He was gazetted Assistant Surgeon 19th Regiment Feb 3, 1843, served with that regiment in the Ionian Islands, the West Indies, and Canada, returning to England in 1851 He was gazetted Surgeon of his regiment in March, 1854, and served as Surgeon of the 19th Regiment in the Light Division of the Eastern Army, from its first taking the field throughout the campaign of 1854–55, until the termination of the siege of Sebastopol, he was not absent from duty one day during the campaign He was present at the affair of Bulganac, battles of Alma and Inkerman, capture of Balaclava, assaults on the Redan June 18 and September 8, and received the medal and three clasps, and the Turkish medal, and was named a Knight of the Legion of Honor He served with the 19th Regiment in the Sepoy Mutiny war until promoted Deputy Inspector-General of Hospitals in 1858 On his return to England he was appointed P M O at Colchester In 1860 he was appointed by Lord Herbert, then War Minister, Professor of Military Surgery at the new Army Medical School, and delivered the opening address in the presence of that Minister, the General Commanding the District, and other officers of distinction

In 1864 he represented the British Government at the International Congress at Geneva At this Congress the International Treaty, since known as the Convention of Geneva of August 22, 1864, was formally adopted, and he was a member of the Committee that settled the terms of the Convention In 1867 he took part, by order of the Secretary for War, in the international conferences of the societies for aid to wounded soldiers in time of war In 1867 he was nominated a Companion of the Military Division of the Most Honorable Order of the Bath, and in the following year he was gazetted Honorary Surgeon to Her Majesty the Queen In 1866 the Société Impériale de Chirurgie de Paris elected him Correspondant Etranger In 1869 he again represented his Government at a Conference in Berlin on Aid to Sick and Wounded in War In 1872, and again in 1873 and 1876, Surgeon-General Longmore represented the British Government at Vienna and Brussels for the settlement of international agreements relating to sick and wounded in war, and took, in a mixed committee of military and medical officers, an active part in establishing the bearer companies, and most of the existing field hospital arrangements of the British Army On five other occasions he represented his Government at foreign congresses, and was elected an Associé Etranger of the French Academy of Medicine and other scientific societies In 1879 he was promoted by decree of the President of the French Republic to the rank of Officier in the Legion of Honor, the insignia of which, by Royal license, he was permitted to wear In 1886 he was knighted by the Queen at Osborne, and in the following year the Military Medical Services presented the fine portrait of Surgeon General Longmore to the Army Medical Department, by George Reid, R S A, of Edinburgh, which adorns the anteroom of the mess-room at Netley

This Journal for August 24, 1895, contained an exhaustive review of Sir Thomas Longmore's last published work

James Collins, M D, died suddenly of heart failure, on the 7th inst, at his home in Philadelphia Dr Collins was 65 years of age, and a native of Pennsylvania He was a well-known surgeon and had been connected with the German Hospital of Philadelphia, as a prominent member of its staff for thirteen years, and was also a member of the American Medical Association He attended the Philadelphia County Medical Society regularly and was a highly valued member At its meeting held September 25, the President being absent, Dr Collins was, on motion, elected chairman *pro tem* He was graduated by the University of Pennsylvania, Medical Department, in 1860 and afterward by Göttingen University He was appointed Surgeon of the 3rd Regiment Pennsylvania Reserve Corps in 1861, and served in the Army of the Potomac, where he was captured and remained in Libby Prison until 1862 He subsequently became Surgeon of Volunteers with the rank of Brevet Lieutenant Colonel He was executive officer at Depot Field Hospital, at City Point, and was mustered out at the close of the war He was a member of the Board of Examiners of Pension Surgeons and was a member of Meade Post, G A R For seven years Dr Collins served as demonstrator of surgery in the Medical Department of the University of Pennsylvania, but although an operator of good judgment and great skill, he was not a fluent speaker, so he gave up this field with reluctance and devoted himself to clinical surgery at the German Hospital, with which he was connected as consulting surgeon at the time of his death Dr Collins was a charitable, amiable and public-spirited man and had a large circle of acquaintances in the upper portion of the city He leaves a widow

Albert E Foote, M D, well known for his devotion to mineralogy and scientific studies, died at Atlanta, Georgia, on the 10th inst, where he was engaged in supervising the mineralogic exhibit of the State of Pennsylvania Dr Foote was born in Hamilton, N Y, Feb 6th, 1846 He was graduated at Ann Arbor in 1867, and afterward remained for a year as instructor in chemistry at the University of Michigan He then accepted a position at the Iowa State College as professor of chemistry and mineralogy and held the chair for five years For the last twenty years, he has resided at Philadelphia, engaged in his profession as mineralogist and in the sale of scientific and medical books He was a member of the American Association for the Advancement of Science, the American Geological Society, the New York Museum of Natural History and of the Academy of Natural Sciences of Philadelphia

Ethan Spencer, M D, formerly of Indiana, but who has been residing in this city with his son, died at the latter's residence, of old age, October 17 Dr Spencer was one of the pioneer physicians of Southern Indiana He was born in New York city in 1812, and when quite a young man removed to Ohio During his stay there he received a land grant from the government to several hundred acres, near Booneville, Ind It was here he first began to practice, later removing to Evansville where he amassed a large fortune He launched into mercantile life and lost his fortune in the panic of 1872 He again began the practice of his profession, in Evansville, where he continued actively at work until about four years ago, when he removed to this city, to live with his son His remains will be taken to Evansville, for burial

J P **Welch, M D**, formerly of Esmeraldo, New Mexico, now of St Johns, Arizona, requests that his friends be notified through the Journal of the death of his wife, which occurred September 21

S F **Rodolph, M D**, of San Francisco, October 9——E W Buck, M D, of Los Gatos, California October 5, aged 68——Michael Price, M D, of Harrisburg, Pa, October 11——J V Holson M D, of Lynchburg, Va, October 11, aged 85——John T Witherspoon, M D, of Lawrenceburg, Ky, October 12, aged 25——Timothy B Cox M D, of Frankfort, Ind, October 16, aged 79——F M Warner, M D, of New York city, October 9, aged 48——R H McFarland, M D of Orlando, Fla, October 9, aged 78——Geo W Davis, M D, of South Jacksonville, Fla, October 9, aged 74

BOOK NOTICES

Transactions of the First Pan-American Medical Congress Held in the City of Washington, D C , U S A , Sept 5, 6, 7 and 8, 1893 In two vols , pp 2,250 Washington Government *Printing Office* 1895

The contents of these two large volumes consist mostly of the papers and discussions read at the first meeting of this great Congress Abstracts of them were flashed by wire to the medical journals at the time, and from time to time for six months after the meeting of the Congress the papers themselves appeared here and there, and as a rule they enriched medical literature But there is much in the book that will be of permanent value The vast work of organization which devolved upon President Pepper, Secretary-General Reed and their colleagues, has its story partially told in the opening of the volume Those familiar with the organization will not need any glimpses behind the scenes to supply the unwritten part of that history

We can not undertake in this brief notice to write a review of these great volumes It is, however, proper that we should caution our Mexican confrères against the repetition of the mistake of too fine subdivision of the Sections General surgery, for instance, was nearly ruined by the intense desire to create new sections, in some cases, after the formation of the originl Section "Orthopedic" Surgery, "Railway" Surgery, "Military" Surgery, Gynecology and "Abdominal" Surgery, "Oral and Dental" Surgery each claimed a separate section This came near destroying the usefulness of the Section Some of them doubtless may be legitimately separated, but the limited discussion of papers that followed such minute divisions was a serious loss to the Congress So far as the papers are concerned, they are in the book under the same roof and the same man may consult all of them at his convenience, but he could not attend the different Sections in which he was interested at the time of the meeting

The importance of this initial meeting can not be overestimated when its bearing on the future of American medicine is considered, and the opportunity which was for the first time afforded of carrying into effect the wishes of the American statesmen who for all these years, since the foundation of our Republic, have wished for closer union politically commercially, professionally and socially The great learning and far-sighted wisdom of President Pepper, the industry and energy of Secretary General Reed and the devotion of the Chairmen and Secretaries of the Sections have made the Congress a creditable one from the standpoint of American medicine, and we doubt not that when the second Pan-American Congress shall be called to order in the City of Mexico, the doings of the first Congress will be taken as a model, and when the Christmas chimes of 1896 are pealing forth a welcome to the adherents of the new Congress, there will be a refrain pleasing to the ears of the constituents of the old Congress, having for its burden, "Well done, thou good and faithful servants "

A Text-Book of Practical Medicine Designed for the use of Students and Practitioners of Medicine By ALFRED L LOOMIS, M.D , LL D , Professor of Pathology and Practical Medicine in the Medical Department of the University of the City of New York, Visiting Physician to Bellevue Hospital, etc Revised and enlarged, with 207 illustrations and 1 chromo-lithographic plate Eleventh Edition, 1,184 pages Price, cloth $6, leather $7

The prefatory note by the publishers states that, "Dr Loomis was actively engaged in the revision of the present volume at the time of his last illness and had completed the greater portion of the work Since his death only such alterations and additions have been made as seemed necessary Dr G C Cokely Dr E D Fisher, and Dr Warren Coleman assisted in the preparation of the present volume "

Few text-books on the practice of medicine in this country have been more widely read than this book of Professor Loomis, and this edition will be referred to with melancholy interest as a posthumous production, although the revision was far advanced when Dr Loomis was stricken with his last illness In this edition the articles on endocarditis, cardiac fibrosis, and cardiac palpitation have been re-written Arrhythmia, tachycardia and brachycardia have been added to the list of cardiac neuroses Dysentery has been placed among the infectious diseases, acute infectious jaundice has been added, and the introduction of malarial fever has been brought in accordance with bacteriologic teachings on the subject The chapter on bacteriology, although brief, gives the essentials on the subject

In regard to antitoxin, after giving the claims of the advocates for it and those of the opposition, the subject is summarized as follows (p 739) "When good observers report so exactly opposite on the effects of antitoxin, it behooves us to administer the substance cautiously, or wait for the results of more extended observation "

It is probable that with occasional revisions this work will continue to hold its enviable position among works on the practice of medicine for many years to come

Herrick's Diagnosis A HANDBOOK OF MEDICAL DIAGNOSIS By JAMES B HERRICK, M D , Adjunct Professor of Medicine, Rush Medical College, Chicago In one handsome 12mo volume of 429 pages, with 80 engravings, and 2 colored plates Cloth, $2 50 Philadelphia Lea Brothers & Co , Publishers 1895

Although, as the author says, this book is intended chiefly for the use of students it will be found extremely useful to all grades of practitioners It is very well written, devoid of circumlocution, and shows throughout that its author is fully competent to write on the subject It may be said to be fairly a Chicago book, inasmuch as it is the outcome of the author's experience in the Cook County and Presbyterian Hospitals It must not, however, be inferred that contemporaneous literature has been ignored, on the contrary, there are few omissions of any important facts

The contents of the book, after the introduction and general considerations, include a discussion of the diagnosis of I, Infectious Diseases, II, Diseases of the Digestive System, III, Diseases of the Respiratory System, IV, Diseases of the Circulatory System, V, Constitutional Diseases, including Diseases of the Blood and Ductless Glands, VI, Diseases of the Kidneys and Genito-Urinary Organs, VII, Diseases of the Nervous System, VIII, Diseases of the Spinal Cord and its Coverings, IX, Diseases of the Brain and its Coverings, and X, Functional Nervous Diseases

It is thus seen that the scope of the work is that of a general medical diagnosis, and the author has made a fair epitome of the entire subject The work is creditable to the author and publisher from every point of view

Foster's Physiology TEXT-BOOK OF PHYSIOLOGY By MICHAEL FOSTER M D , F R S Prelector in Physiology and Fellow of Trinity College, Cambridge, England New (Sixth) American Edition with notes and additions In one handsome octavo volume of 922 pages, with 257 illustrations Cloth, $4 50, leather, $5 50 Philadelphia Lea Brothers & Co

When a book has passed to its sixth edition there is little that can be said by the reviewer which will either make or mar the book and there are few text-books on physiology better known in this country or in Europe than that of Foster In this American edition a strong effort has been made to eliminate all superfluous words and condense it as much as possible Few practitioners, either in general or special practice, keep abreast of the advances in physiology, and this is the more lamentable because of the great aid a knowledge of this branch of science is in every single medical or surgical specialty No practitioner can read a recent book on physiology without being greatly benefited by it Our knowledge of pathologic processes must bear certain and definite proportion to our knowledge of the operations of the body in health, and he who neglects the study of physiology deprives himself of one of his most certain supports The book under consideration has been carefully revised and will be found fully up to date It has almost become in this country as in England as standard as "Gray's *Anatomy*"

Taylor on Venereal Diseases The Pathology and Treatment of Venereal Diseases By Robert W Taylor, A M, M D, Clinical Professor of Venereal Diseases in the College of Physicians and Surgeons, New York In one very handsome octavo volume of 1,002 pages, with 230 engravings and 7 colored plates Cloth, $5 50, leather, $6 50 Philadelphia Lea Brothers & Co, Publishers 1895

This book is the direct successor of the well-known work of Bumstead and Taylor on venereal diseases, and gives the author's conclusions as a result of his own extensive researches and wide experience To this he has added the results of a careful sifting of the literature of the subject down to the present time The book is divided into three parts as follows Part I, forty-two chapters devoted to gonorrhea and its complications Part II, seven chapters, devoted to chancroid or soft chancre Part III, thirty-eight chapters, devoted to syphilis As an exhaustive treatise on the subject, at the same time one that is painstaking and accurate, it will be a work to which the surgeon will turn for reference whenever he has occasion to study the subject The dosage is partly in the decimal, and partly in the old system, that is, when a continental author is quoted the decimal system is used The book is in every way creditable and affords a further illustration, if any were needed, that in these days it is not necessary to buy a foreign book in order to keep fully abreast of the scientific knowledge of the day We are confident that Dr Taylor's work will meet with even more pronounced success than the former works in which he was engaged with the late Dr F J Bumstead

Surgery A Practical Treatise with Especial Reference to Treatment By C W Mansell Moullin, A M, M D, Oxon Assisted by various writers on special subjects With 623 illustrations, many of which are printed in colors, about 200 having been made from special drawings Third American Edition, revised and edited by John B Hamilton, M D, LL D, etc Cloth, pages 1,250 Philadelphia P Blakiston, Son & Co 1895

In the prefatory note to this edition, the editor states that the entire work was passed through the press in the period of six weeks—a most unusual record even in this age of many improved facilities The revision of this book was undertaken with the express purpose of striking out every superfluous word in it, leaving nothing but the solid text, and then to add whatever was new that was necessary to bring it in harmony with the latest teachings on the subject New illustrations have been added, and it may be confidently stated that the book is not surpassed by any single volume text-book of surgery on the market for the use of general practitioners and students The illustrations are from the latest text-books, and those examining the work will find that omissions are very few

Gray on Nervous and Mental Diseases A Treatise on Nervous and Mental Diseases By Landon Carter Gray, M D, Professor of Diseases of the Mind and Nervous System in the New York Polyclinic New (Second) Edition, In one very handsome octavo volume of 728 pages, with 172 engravings and 3 colored plates Cloth, $4 75, leather, $5 75 Philadelphia Lea Brothers & Co, Publishers 1895

It is a pleasure to write a notice of a book of this character The well-known literary attainments of the author, the fine paper and beautiful text, the elegant illustrations, many of which are in colors, make it easy to understand why this book has passed to a second edition Five new chapters have been added in this edition, namely Dementia, Dementia Paranoides, Confusional Insanity, Delirium, and Massage "The word treatment," says the author, "has been construed in the broadest sense to include not only medicinal and non-medicinal agents, but also those hygienic and dietetic measures which are often the physician's best reliance"

In regard to massage, the author says "In cases of individuals who, for various causes, are unable to use their muscles, or in others who are necessarily confined to their room or to bed, massage is an invaluable therapeutic agent The great difficulty about it is there are few persons expert in the giving of it For several years I almost abandoned its use for this reason, and it has only been since I have kept in my employ a masseur that I have been able to rely upon it In some instances I have known physicians instructing some nurse so as to obtain very creditable results"

This edition will be found carefully revised and brought up to date with the exception of the prescription writing, in which the old system of dosage is still adhered to The book will be found as interesting as its predecessor and retaining all of the characteristics which made the first edition popular

Synopsis of a Course of Lectures on the Anatomy, Physiology and Histo-Chemistry of the Nervous System By John A Benson, M D Chicago E H Colegrove & Co 1895

This is a complete syllabus of a course of lectures on its titular subject, in which the author's experience as a physiologist and his practical ability as a teacher are well displayed We commend the syllabus to those who are interested in the subject

Case Recorder in General Medicine and Gynecology, for the Use of Physicians, Students, Dispensaries and Hospitals By S B Lyon, M D Milwaukee A L Koursh & Co 1895

We have examined this clinical record with some care, and have to say that for minuteness and completeness we have not seen its equal Every possible symptom has a place wherein it can be recorded, and those who desire to keep accurate records of their patients will find this a most useful record book

Bernd's Physicians' Register St Louis, Mo Henry Bernd & Co

This register is admirably adapted for the keeping of accounts with patients, and doctors who are said in some quarters to be poor business men, can be made good ones, so far as the keeping of their accounts is concerned, if they will take pains to provide themselves with this admirable record

MISCELLANY

Septicemia —The latest treatment for general septicemia is hypodermic injections of creasote The creasote is mixed with equal parts of camphorated oil, and 20 minims of the solution are injected three times a day —*Journal of Practical Medicine*, October, 1895

Illinois State Medical Society —The Transactions of the Illinois State Medical Society were sent to the members last week by express Those who are in arrears may receive the volume by at once remitting their annual dues to the Treasurer, George N Kreider, M D, Springfield, Ill

Medical Advertisements —In its issue of October 15, *The Medical Fortnightly* gives notice that it has adopted the rule that it will not accept advertisements of medical preparations, the proprietors of which do not give a formula containing the official or chemic name and quantity of each composing ingredient to be inserted as a part of the advertisement

Hospitals in Jerusalem and Damascus —An English medical missionary, Dr Masterman, at present residing at Jerusalem, reports that progress is being made with the erection of the new mission hospital at Jerusalem The hospital will have beds for forty patients, and will also have a dispensary It is outside the city, on the freehold property of one of the London societies known as the "Sanitarium," about three-quarters of a mile from Jaffa Gate A hospital at Damascus will shortly be opened Dr Masterman will take charge of the work for a year, at the expiration of which time a permanent medical appointment will probably be made

Parvin on Boerhaave —In the *Medical and Surgical Reporter* is quoted a letter from Dr Parvin, narrating his medico vacational tour through Holland He found much to interest him in the Dutch cities, inclusive of Leyden Of that city he writes " Leyden interested me chiefly because there Boerhaave lived and taught It seems to me that Medicine has given the world few greater, and none better than he His monument, with its brief inscription, scarcely more than date of birth and date of death, reveals a man of commanding appearance, and of large head, with prominent fore head "

Divorce Denied —A cruel statement is telegraphed from Kansas City, to the effect that one of the 'New Women" who practices medicine in that town, was refused a divorce by an unfeeling judge, who asserted that the reasons urged by her were insufficient to warrant the issuance of a dêcree It seems that the bill of the plaintiff alleged that the wicked husband refused to cook the meals while she was engaged in daily practice of her profession, and that he would not even help her prepare the meals, but 'laid around" while she was thus engaged The complainant's tale of woe is probably unique, and deserves more mention than it is likely to receive

An Old Garbage Dumping Ground —Riker's Island, near New York city, was for a time used as a dump for garbage This use was perforce abandoned on account of the villainous odors caused thereby The subsequent story regarding the place is interesting, as showing how difficult it is to throw anything away One of the New York papers tells that story as follows " Riker's Island was a barren aggregation of rocks, not too far from New York to be reached and not near enough to be noticed. It seemed a handy spot to dump garbage and garbage accordingly was dumped on it The garbage smelled bad, so earth was spread on top of the garbage Then it was left alone It began to smell bad again about a month ago, and its neighbors complained Then an explorer was fitted out to investigate it He came back with a great load of vegetables, and the surprising tale that Riker's Island had dreamed it was a kitchen garden, and that the dream had come true The vegetable seeds in the garbage had grown up through the top-dressing of soil, and behold profusion itself—melons, pumpkins, squashes, tomatoes, and other fruits of the earth glowing and ripening in their seasons, with no one to hinder and no one to glean "

Progress of Dentistry in Japanese Cities —An eminent correspondent of the New York *Herald*, having been inquired of regarding the field for American dentists in Japan, has written a letter discouraging in its tenor, that is abstracted in the following " Japan is full of dentistry, and the native dentists are flourishing There is a dental department connected with the medical branch of the Tokyo Imperial University There are fifty six practicing dentists in Tokyo, and each office has from four to twelve students These young men assist at all operations One works the drill, another handles the syringe, another passes up the gold foil, and the division of labor is quite scientific Many of the Japanese dentists are graduates of firstclass American colleges They are quite skillful The Japanese are fond of having their front teeth filled with gold They frequently have holes bored in good teeth in order to have them plugged and polished They think that the exhibit of gold fillings in front teeth suggests advanced civilization San Francisco turns out about one hundred young Japanese dentists a year There is a factory in Tokyo which turns out all manner of dental instruments and dental goods, including engines and porcelain teeth "

Distribution of Population in New York and Philadelphia, London and Paris —The New York *Sun* contains some census comparisons that are of interest to medical readers, showing how the people of certain large cities in this country and Europe are housed New York has 115,000 houses, averaging 18 residents to each London, the greatest accumulation of inhabitants in the world, has 600,000 houses, or 7 residents in each on the average London has increased in this respect very rapidly, for at the beginning of the present century the number of houses was only 130,000, little more than New York has at the present time The population of London at that time was 960,000 It is now 4,200,000 So it has increased nearly fivefold, but the number of houses has not increased in as large a ratio Paris has 90,000 houses At the close of the Franco Prussion war it had 70 000 At the close of the Napoleonic wars it had 28 000 The area of the city has been extended meanwhile The average number of residents in a house in Paris is 25, which is about 50 per cent greater than in New York In all computations of city population by houses, Philadelphia ranks as a shining example of a big town which has plenty of "elbow room" to expand in Philadelphia, with a population in excess of 1,000,000 has 137,000 houses It is less densely populated than London, but not much less so

Pharmacy Law of Oklahoma —The pharmacy law of the Territory of Oklahoma has been amended so that it is in part as follows, the old provisions on the same subject being inclosed in quotation marks "Any person in order to be qualified [as a pharmacist], shall be 21 years old, and shall have passed a satisfactory examination before the board of pharmacy of the Territory of Oklahoma," or shall produce a certificate of pharmacy, regularly issued to him under the authority of any State or Territory, and prove that he is in good standing in that State or Territory, 'or shall be a graduate of pharmacy, as hereinafter provided " *Provided, however*, That nothing in this chapter shall be construed to prevent any physician duly authorized to practice medicine in this Territory from keeping drugs for use in his profession, and compounding his own prescriptions Pharmacists having passed the examination provided by the board of pharmaceutic examiners, and being duly registered, as provided by law, it is also enacted, are to be exempt from all jury service

Milk Typhoid at Simla in Northern India —The *Sanitary Record* has an item referring to the outbreak of fever at Simla, a summer resort for Indian officers and Europeans doing business in and around Bombay and other cities It says "Several cases of typhoid fever which have occurred lately are attributed by Dr Cunningham to the sale of impure milk brought in from villages in the surrounding native States Dr Cunningham has addressed a very strong remonstrance to the Municipal Committee on the subject, and urges the necessity of immediate action being taken "

Congenital Unilateral Absence of the Kidney —Ballowitz (*Virchow's Archiv*, Bd 141, Heft 2), makes a literary and statistic study of 210 cases of congenital absence of one kidney and adds three cases of his own

The combined statistics of Brown (*Journal of Anat and Phys*, xxviii, 1894) Morris (*Brit Med Journal*, 1885, vol i, p 814), Sargalli (*Reale Instituto Lombardo Rendicont*, Ser ii, vol ix, 1876), Mensies (*Jour Anat and Phys*, vol xxi, 1887), and Rootes (*Lancet*, 1866, vol ii, p 251), show one kidney to have been absent eleven times in 27,806 post-mortem examinations Of the 213 cases of single kidney collected by Ballowitz the defect occurred one hundred and seventeen times on the left side and eighty eight times on the right In 112 male bodies the kidney was absent seventy times on the right side and forty-two times on the left In sixty-five female bodies the left kidney was absent thirty one times the right thirty-four times Consequently the figures show that single kidney is found nearly twice as often in male as in female bodies, and that in the male bodies the left kidney is much more frequently absent than the right When a kidney is absent the corresponding renal vessels are practically always also absent The ureter was also absent except in fifteen cases The shape of the single kidney is generally

Health was called on the 15th inst by the Chairman, Dr Samuel C Busey Important business was discussed relating to sewers, water supply, milk supply and inspectors, and the annual report of the Committee

Medical Society of the District —At the meeting of the Society held on the 16th inst, Dr Bovee presented three specimens of fibroids recently removed Dr B A Storck read a paper on puerperal septicemia and antisepsis Both subjects brought out a full and interesting discussion The following resolution touching the question of typhoid fever in the District was adopted

"*Resolved*, That the Medical Society commends the efforts of the Health Office to ascertain the number of cases of typhoid fever in the District, and that the corresponding secretary be instructed to send a circular letter to every member of this body, urging him to report at once to the Health Office the number of cases of typhoid fever he has treated since July 1, 1895, and if he has not had any cases to report that fact "

Washington Obstetrical and Gynecological Society — The two hundred and thirty-third meeting of the Society was held on the 8th inst at the Arlington Hotel This was the annual business meeting for the election of officers and committees, and resulted as follows President, Dr Geo Byrd Harrison, Vice-Presidents, Dr Geo N Acker and S S Adams, Secretary, Dr G W Cook, Treasurer, Dr John Van Rensselaer, Corresponding Secretary, Dr W S Bowen Business Committee, Drs Winter, Nash and Bowen Admission Committee, Drs Spriggs, Deale and Cuthbert Publishing Committee, Drs Deale, Spriggs and Cook The Society will entertain the Southern Gynecological Society at its meeting here in November, and appointed a committee to make arrangements At the close of the meeting the members sat down to one of the finest banquets ever served in the "Arlington "

Microscopical Society —The annual meeting of the Society was held on the 8th inst The following officers were elected President, Dr Marshall, Vice-President, Dr Gibbs, Treasurer, Dr Bullock, Secretary, Mr Mooers A banquet will be held next month

Medical Society of the District —At the meeting held on the 9th inst, Dr Shands read a very interesting paper entitled, "The Importance of Early Mechanical Treatment in Anterior Polio myelitis" A free discussion followed Dr J T Johnson presented cases and specimens, viz, concretion from an appendicitis, extra uterine pregnancy, ovarian cysts and two hysterectomies

Central Dispensary and Emergency Hospital —The regular monthly meeting of the Board of Directors of the hospital was held on the 11th inst The following appointments as assistants, were made by the staff and approved by the Board Drs H S Goodall, Wallace Johnson, Ada R Thomas, Rupert Norton, Walter A Wells, E E Morse and Maxwell H Allen

Recommendations of Excise Board —The excise law of the District does not provide protection against the adulterations of liquors by dealers or others, hence the Excise Board submitted the following to the Commissioners of the District, with the request that they urge its passage by Congress

"Every person so licensed, or any other person who shall intentionally or otherwise sell or give away or direct or permit any person or persons in his employ to sell or give away, malt, spirituous and vinous liquors which shall be adulterated with strychnin, strontia, sugar of lead or any substance which is poisonous or injurious to health, shall forfeit and pay the sum of $300 for every such offense, and in case of non-payment of such fine shall be imprisoned in the jail of the District of Columbia for a period of time not exceeding six months or till the same is paid An analysis made by a practical chemist shall be deemed competent testimony under the provisions of this section "

The Post Graduate School of Medicine of the District of Columbia —The following named gentlemen met on the 10th inst at the office of Dr H L E Johnson, and organized the Post Graduate School of Medicine of the District of Columbia Dr H L E Johnson, E L Tompkins, W W Johnston, Samuel C Busey, J Foster Scott, H D Fry, S S Adams, J Ford Thompson, T E McArdle, Chas W Richardson, James Kerr, G N Acker, W H Wilmer, M F Cuthbert, E M Parker, G Wythe Cook and George Byrd Harrison The meeting was called to order by Dr Johnson, and Dr Samuel C Busey was unanimously elected President Upon motion the President appointed a committee to draft a constitution and by-laws The meeting adjourned pending the report of the committee

---

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from October 10, 1895 to October 17 1895

Major B F Pope, Surgeon U S A, is granted leave of absence for thirty days

Capt Julian M Cabell, Asst Surgeon, ordered to Davids Island, N Y, for duty in lieu of reporting to the Surgeon General for duty

Major Henry M Cronkhite Surgeon, having been found incapacitated for active service is retired to date from Sept 17 1895

First Lieut Isaac P Ware, Asst Surgeon, is granted leave of absence for one month, on surgeon's certificate of disability, with permission to leave the limits of the Department

First Lieut John S Kulp, Asst Surgeon U S A, is granted leave of absence for one month, to take effect about Nov 10, 1895, with permission to apply to the Adjutant General of the Army for an extension of one month

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending October 19 1895

Medical Directors G S Beardsley and P S Wales, ordered to duty as members of the naval examining and retiring board

P A Surgeon J S Sayre, ordered to treatment at the Philadelphia Naval Hospital

P A Surgeon C H T Lowndes, detached from the naval hospital at Mare Island and ordered to the Marine Rendezvous, San Francisco, Cal, and in attendance on officers in that city

P A Surgeon C J Decker detached from the Marine Rendezvous and special duty in San Francisco, and ordered to the naval hospital at Mare Island

APPOINTMENT

J C Rosenblueth appointed Asst Surgeon in the Navy, October 14

Marine Hospital Changes Official list of changes of station and duties of Medical Officers of the U S Marine Hospital Service, for the fifteen days ended October 15, 1895

Surgeon R D Murray, granted leave of absence for thirty days, Oct 4, 1895

Surgeon Fairfax Irwin, granted leave of absence for thirty days, Oct 4, 1895

P A Surgeon C E Banks, detailed as chairman of board for physical examination of officer and candidates, revenue cutter service, Oct 2 and 8, 1895

P A Surgeon S D Brooks when relieved from temporary duty at St Louis Mo to rejoin station at Chicago, Ill, Oct 3, 1895

P A Surgeon G M Magruder, upon completion of duties at Camp Jenner, Eagle Pass, Texas, to rejoin station at Galveston, Texas, Oct 11, 1895

P A Surgeon L L Williams, to proceed from Charleston, S C, to Waynesville, Ga, as inspector, Oct 2, 1895

P A Surgeon J O Cobb, to proceed to Victoria B C, and Vancouver, Wash, on special temporary duty Oct 12, 1895

P A Surgeon B W Brown, detailed as recorder of board for physical examination of officer and candidates, revenue cutter service Oct 2 and 8, 1895

P A Surgeon E R Houghton granted leave of absence for thirty days from date of being relieved from duty at Vineyard Haven, Mass, Oct 5, 1895

Asst Surgeon Emil Prochazka, when relieved from temporary duty at Charleston, S C, to proceed to Cairo, Ill, for temporary duty, Oct 12 1895

Asst Surgeon A R Thomas, relieved from temporary duty at New Orleans La and directed to rejoin station at St Louis Mo Oct 3 1895

Asst Surgeon J B Greene, relieved from temporary duty at Wilmington N C, and directed to proceed to Vineyard Haven, Mass, and assume temporary command of the Service, Oct 2, 1895

RESIGNATION

P A Surgeon E R Houghton, resignation accepted, to take effect upon expiration of leave of absence, Oct 5, 1895

ADDRESSES

INTRODUCTORY ADDRESS

Delivered at the Chicago Medical College

BY EDMUND ANDREWS, A M, M D, LL D
CHICAGO

DO NOT LET YOUR LATIN SPOIL YOUR ENGLISH

You have all prepared yourselves with some knowledge of Latin and Greek to assist your medical studies Many of you have received degrees from colleges and universities such as Bachelor of Arts, Bachelor of Sciences, Master of Arts, etc, given as honors for your hard study in these and other branches Your knowledge of Latin and Greek will immensely facilitate your understanding and memory of technical terms, as well as promote your skill in writing prescriptions and will prove a valuable element in your mental culture To this end and to this extent, you may well be glad of your knowledge of the classic languages Connected with this knowledge, however, there is a peril besetting the development of your literary style It is the danger of allowing Latin and Greek derivatives to crowd unnecessarily into your speech and writings, corrupting the purity of your English, and giving to your productions an air of stiffness and pomposity

It is true that many organs in the human body, and many physiologic processes have no English names, and we are compelled to make use of a certain number of technical terms borrowed from the Latin and Greek, but words of this group are long and generally harsh in sound, and they work roughly and badly in the construction of English sentences They should be used therefore as sparingly as possible They do not harmonize well with Anglo Saxon speech

High literary authorities condemn the needless loading of sentences with these half foreign words If a new word has to be composed to express a new and unnamed fact, make it as short and as smooth in sound as possible, remembering that pure, simple, crystalline English constitutes the best style Do not spoil it by loading it down with pompous polysyllables of Latin and Greek origin

That master of good style, James Russell Lowell, laments our inferiority to English writers in this respect He says "It has long seemed to me that the great vice of American writing and speaking is a studied want of simplicity Very few American writers wield their native language with the directness, force and precision that are common as the day in the mother country While the schoolmaster has been busy 'starching' our language and smoothing it flat, the newspaper reporter has been doing even more harm by stretching and swelling it to suit his occasions" Such is Lowell's opinion

Short Anglo Saxon words of common use are the best, wherever they will express the meaning It is this choice of short words, resulting in a condensed style of singular force, which gives the writings of Shakespeare and the English translation of the Bible much of their tremendous power

It is amusing and yet vexatious to see a worthy medical gentleman whose ordinary conversation is in a simple and good style, suddenly swell up when he writes a medical article He changes his whole dialect and fills his pages with a jangle of harsh technical terms, not one-third of which are necessary to express his meaning He tries to be solemn and imposing For instance, a physician recently devised a new instrument, and wrote it up for a medical journal under this title, "A New Apparatus for the Armamentarium of the Clinician," by which heading he doubtless hopes to make the fame of his invention, "go thundering down the ages" as Guiteau said

Another writer wanted to say that cancer is an unnatural growth of epithelium He took a big breath and spouted the following "Carcinoma arises from any subepithelial proliferation by which epithelial cells are isolated and made to grow abnormally" Now, then, you know all about cancer

A writer on insanity illuminates the subject as follows "The prodromic delirium is a quasi-paranoiac psychosis in a degenerate subject A psychosis of exhaustion, being practically a condition of syncope"

The following is an effort to say that certain microbes produce the poison of erysipelas "The streptococcus erysipalatosus proliferating in the interspaces of the connective tissue is the etiologic factor in the secretion of the erysipelatous toxins"

A large cancer of the liver was found at a postmortem examination and reported about as follows "A colossal carcinomatous degeneration of the hepatic mechanism"

Still, the man of big swelling words is not always up in the clouds If called to a case of accident, he examines the injury, and may inform the family in quite a simple and dignified manner that their father was thrown sidewise from his carriage breaking his leg and putting his ankle out of joint, but if he writes out the case for his medical journal, he gets up straightway on his stilts and says "The patient was projected transversely from his vehicle, fracturing the tibia and fibula and luxating the tibio-tarsal articulation"

Your man of solemn speech is peculiar He does not keep a set of instruments—not he—he has an armamentarium His catheters never have a hole or an eye in them, but always a fenestrum In gunshot injuries, a bullet never makes a hole in his patient, but only a perforation He does not disinfect his armamentarium by boiling, but by submerging it in water elevated to the temperature of ebullition He never distinguishes one disease from another, but always differentiates or diagnosticates it His patient's mouth is an oral cavity His jaw is a maxilla His brain is a cerebrum, his hip joint is a coxo-femoral articulation If his eyelids are adherent, it is a case of ankylo-symblepharon If he discovers wrinkles on the skin, they are corrugations or else rugosities He never sees any bleeding, but only hemorrhage, or sanguineous effusion He does not examine a limb by touch or by handling—he palpates or manipulates it If he finds it hopelessly diseased he does not cut it off—that is undignified He gets out his armamentarium and amputates it

I like the sturdy contempt of our English brethren for all mere word pomp and prudishness In London they still call their most fashionable avenue for horseback riding by its ancient name of "Rotten Row " In Chicago we would long ago have changed it to "Grand Washingtonian Cavalry Boulevard "

The surgeon over there generally shows the same solid traits as their other writers, and you will do well to study the writings of the eminent Frederick Treves of London, as a model in this respect

A good British surgeon has good culture and good common sense combined He takes his trocar and taps a dropsy, for instance Not so the American He blushes to hear such plain speech from his British brother, but he takes his armamentarium and goes out straightway and performs paracentesis abdominis Still the pompousness is not all on one side of the ocean, and it is refreshing to see an occasional touch of it beyond the seas, just to show that we are not the only sinners in this respect

A celebrated British surgeon explains his opinions as follows "Septic peritonitis, save where definable from evidence wholly extrinsic to the condition of the peritoneum, is an etiologic entity which exists only in the mind of the pathologic metaphysician " Nothing worse than this was ever written on our side of the water

Two of the stilted phrases which have recently gotten into vogue are etiologic factor and etiologic entity They are both snobbish substitutes for the plain English word, cause

The Greek word 'αιτια, means a cause 'Αιτιολογια, from which we derive etiology, is compounded of 'αιτια, cause, and λογος, which taken in composition means a study or science The whole means the science of causes 'Αιτιολογιχος, from which we derive etiologic, means a person skilled in the study of causes, or a thing pertaining to the science of causation Factor is a Latin word, lugged in improperly, to mix with the Greek It is of the masculine gender and signifies a man doing or producing something As an English word it also has a mathematical use Putting the whole jumble in order, an etiologic factor ought to mean some person or thing skilled in, or related to the science of causes, or, in other words, a causative-science maker, or a maker of something or of somebody pertaining to the science of causation In the name of all the gods of Greece and Rome, what idea are these men trying to express? If they mean cause why don't they say cause and be done with it? Language is not manufactured, it grows The speakers of each tongue have evolved it through the ages by the process of trying thousands of new words, and instinctively rejecting such as lack the music and fitness required for speaking purposes They have tried all ways of molding words into sentences until the perfected language, like mosaic work in the hands of some great master, has become fitted to express all the high and inspiring thoughts of men

Such a language is the pure English of to-day Derived mainly from the Anglo-Saxon, its words are chiefly monosyllables, but they are all gems, and all polished and fitted to each other by ages of use Whoever is master of it, is an artist in the highest sense Whoever thrusts into it a rough, harsh, polysyllabic word, crudely quarried out of a Greek or Latin dictionary, is like a fool who drives a pickaxe through a magnificent mosaic picture, and then plugs the hole with a brickbat

The author who dumps upon us a book full of long and ragged new words, merely to display his knowledge of ancient languages, shows his ignorance of English, and brands himself as a bungler and a literary blockhead

As I said before, use newly coined words sparingly, but when they become necessary, select them as carefully as you would choose jewels for your bride Fit them, polish them, and make them suitable for flashing forth the best thoughts of human souls

It is curious that the half-educated man who knows little or nothing of the classics, always dotes most on these big phrases, and is ever foremost in piling up the abominable rubbish-heap of long, scraggy words which deform medical literature, and render it a melancholy spectacle to gods and men

The evil is intolerable, and in your day a reform will be demanded Bear in mind that your lives are to be spent in an atmosphere of higher culture than that of your predecessors

The finer culture of the future will demand a reorganization of our word system, and will cast to the moles and the bats very much worthless material which is now the pride of the ignoramuses who invented it Prepare yourselves therefore for the change, and do your best to make the language of future science more bright, pure and simple, and more fit for the use of all who wish to couple clearness of thought with beauty of expression

---

SOCIOLOGY AND CRIMINOLOGY

Address at opening of Department of Sociology and Criminology, at the Medico Legal Congress

BY CLARK BELL, ESQ

NEW YORK

That public interest in sociologic studies is on the increase in our day, can not be questioned We may recognize its hold on popular thought, by remarking that in the present Congress more papers are contributed to the Department of Sociology and Criminology, than to any other This is not in my opinion the result of chance, but is due to the increasing interest manifested in the world of thought in this domain of scientific investigation

Especial stimulus has been given to the study of criminology by Lombroso's writings, and others of his school

Enricco Ferri has touched it with his brilliant lance Herman Kornfeld, Morris Benedikt, Kraft Ebbing, Morel, Le Grand du Saulle, Brierre du Bois Mont and Prosper Depine on the continent, Havelock Ellis, W W Ireland, Pritchard, Thomson, Dr Nicholson and W Douglass Morrison in Great Britain, and many other writers of distinction have illumined its importance The International Congress of Penal Law, attracted twice, many great names from all the world, to this subject

It is not crime alone that we study now, with method of punishment, sentences, prisons and their management, including discipline and corporal punishment in prisons, all the offenses and the modifications in penal statutes, but we are coming to study more, the criminal himself, his characteristics, degeneracy, heredity, and above all environment

Are punishments for crime, as defined in our penal statutes, really deterrent? Has the State the moral right to inflict punishment in any retaliatory spirit as is now oftentimes the basis of penal statutes? and if experience demonstrates that excessive or prescribed forms of punishment do not act in fact as a deterrent in diminishing crime, should we not consider with greater care what modifications are proper to reach the end desired, beside the protection of society, a perceptible decrease in the volume of crime?

The lesson of the repeal of long list of capital offenses in Great Britain since the day when sheep stealing was a capital offense, must not be lost Severity of punishment does not appear to operate as a deterrent It seems to be true that the fear of the scaffold rarely deters the murderer

Crime seems in the ocean of humanity, to be the sum of social causes, which, like great rivers, flow toward and empty into it Its Amazon is, no doubt, alcoholic stimulants which more than all other causes combined, constitute the inevitable, terrible, irresistible scourge of the race In its currents, tides and eddies, are insanity, epilepsy and physical degeneracy, not always in the parent, but more certain in the offspring Its movements run like the blood of man into the veins and lives of children's children, with a taint as terrible as that of leprosy or syphilis

The burdens to the State for the care of the insane in the rural districts or counties, notably in an agricultural county like Yates, where I reside in the summer, in this year of grace is actually greater than the cost of the schools, and almost equal to the entire other expense of the State government including the canals

When will we have the courage to look this awful question squarely in the face, and decrease the volume of crime, not by penal laws for the punishment of the criminal (often the victim of his birth and environment) but by striking at and repressing the cause

The recognized defects in our penal laws, especially in Great Britain, the United States and many of the continental states may be summarized as follows

1 The principle of equality of sentences, as to their duration as now existing, is erroneous and vicious in its fundamental principles

2 It is wrong to make arbitrary punishments for the same offenses against all offenders alike

3 Criminal laws must be so framed as to meet the social conditions of the criminal classes

Laws based upon the social conditions of men in the ordinary walks of life, fail They should rather be aimed at the social life and condition of the criminal classes I quite agree with W Douglass Morrison of the Wadsworth Prison in England, when he asserts that "The criminal is a product of anomalous biologic conditions, as well as adverse circumstances "

4 Some plan should be devised in the administration of punishments to offenders, under which the principle of determinate sentences should be applicable to the individual condition of the offender For example (*a*), the same offense should not receive the same punishment in all cases, as for example, when committed by an adult, or a child or a youthful offender, (*b*), the difference in punishment for the same offense by a man and by a woman, should be rather to *the* man and *the* woman

5 We must consider whether Bentham was right in insisting that we should, in adjusting our methods of punishment, look as much to the nature and condition of the offender as to the nature of the offense Much of the failure of our present system as a protection to society is unquestionably due to our ignoring this fundamental law in our present penal statutes, and punishment of criminals

Mr Morrison strikes at an important principle, that we should place our prisons on the same basis as the penal laws That prisons should reach the causes and conditions which produce the criminal, and the penal statutes be placed on the same plane

PROGNOSTIC SIGNIFICANCE OF ALBUMINURIC RETINITIS

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md , May 7-10 1895

BY E OLIVER BELT, M D
PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, HOWARD UNIVERSITY, AND OPHTHALMIC AND AURAL SURGEON TO FREEDMAN'S HOSPITAL
WASHINGTON D C

It seems to be generally admitted that the retinitis following scarlet fever and pregnancy is not of special prognostic significance as to vision or mortality, for under careful treatment recovery of both vision and health are not unusual in these cases Therefore in this paper, such cases have been excluded, as the prognosis is altogether different and unfavorable in the retinitis of chronic Bright's disease Though improvement of vision very frequently occurs in albuminuric retinitis, it is of minor importance in comparison with the life of the patient, and the main point which I wish to determine is the average duration of life after the appearance of retinitis from renal disease The statistics heretofore published upon this subject deal mostly with hospital cases, in which the duration of life rarely exceeds one year Occasionally we see reported a case in private practice which has survived five, ten, and even fifteen years (Noyes mentions one of ten years, and Webster reports the case of a minister who survived seventeen years) This led me to think that we might be able to give a more hopeful prognosis in cases which could receive good medical attention with the proper hygienic surroundings, and I decided to try and find, whether or not the average duration of life was greater among private than among hospital cases With this end in view, a few weeks ago I requested quite a number of ophthalmologists throughout the country to report the cases which had occurred in their private practice to me The time allowed was too short for many to look over their records, and many had not kept trace of the patients after referring them back to the family physician, but enough cases were reported to show that the duration of life is longer among private patients, and that renal affection is undoubtedly influenced by hygienic sur-

roundings However, the number of cases surviving two years was disappointingly low, and the consensus of opinion, as shown from the following extracts from letters received, seems to be that nearly all prove fatal in less than two years

Dr G E de Schweinitz, of Philadelphia, says "So far as I know, there is no case in my private practice that has lived longer than two years after the development of the retinitis "

Dr J L Thompson, of Indianapolis, says "Have had between fifty and one hundred cases scattered through my books in a private practice of twenty-four years Several of my patients have died within thirty days, while others have lived two years Many more died within six months after its first manifestation in the eyes than lived after that period "

Dr Walter B Johnson, Paterson, N J, says "In many cases the retinitis was the first indication of kidney disease, which after discovery almost invariably progressed very rapidly "

Dr Peter D Keyser, of Philadelphia, says "That the length of life depends upon the retinal appearance at the time of the first examination In well marked cases, I should say an average of twelve months, if the patient is under good medical care I have had some cases to run two years, others only three months "

Dr L A W Alleman, Brooklyn, N Y, says "Save in some cases due to pregnancy, I have never seen a pure case of albuminuric retinitis last over a few months, from the time it has come under my observation "

Dr Samuel D Risley, Philadelphia, says "My impression is that after the appearance of eye symptoms, nephritis is rapidly fatal I recall cases of death occurring within a few weeks, and can not recall one which did not prove fatal inside of two years, whether associated with pregnancy or not "

Dr G C Savage, Nashville, Tenn, says "My recollection of these cases is that they died within two months, and I do not remember that a single case lived longer than five months "

Dr Charles W Kollock, Charleston, S C, says: "In no case in my practice has any such patient lived out the year "

Dr Peter A Callan, New York, says "My impression is that the great majority die under two years after the onset of the retinal changes, but there are exceptional cases, one of which has now lived nine years since I first made out that she had the kidney trouble with the eye complication ”

Dr George T Stevens, New York, says “I observe that some of our colleagues think that a fatal termination is to be expected within a few months after the discovery of the albuminuric retinitis I can recall to mind quite a number of people who have survived several years Mrs K survived more than eleven years after I found well-marked retinitis albuminuria This is not, I think, a specially exceptional case ”

Dr David Coggin, Salem, Mass , says “Of thirty fatal cases, I remember but two who lived over six months ”

Dr C S Turnbull, Philadelphia, says “My experience has in a general way led me to think that the time is most variable, depending greatly upon the many and varied forms of renal disease in different individuals ”

From all the statistics I have been able to find, we get the following results Cases in private practice 155, of these 62 per cent died within one year, 85 per cent in two years, and 14 per cent lived more than two years

Hospital cases, 77 of these, 85 per cent died within one year, 93 per cent in two years, and 6 per cent lived more than two years

Mixed cases, 187 of these, 65 per cent died within one year, 93 per cent within two years, and 6 per cent lived more than two years

Total number of cases, 419, of these, 72 per cent died within one year, 90 per cent within two years, and 9 per cent lived more than two years

EXTENSIVE COLLOID CHANGES IN THE CHOROID, WITH REPORT OF CASES

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY JOHN T CARPENTER JR , M D
PHILADELPHIA, PA

In some of the text books on ophthalmology mention is made of a senile change in the fundus oculi, characterized by the appearance of small yellowish and yellowish white spots which have been regarded as hyalin or colloid degeneration in the lamina vitrea choroidea In Noyes we find a full description under the head of degenerative changes of the choroid, in which he assumes the identity of drusen and this colloid degeneration of the lamina vitrea He calls attention to the clinical fact that vision is not impaired in these cases Two excellent colored plates representing two varieties of the affection are shown, to both of which I wish to call attention In one, the large, globular, mulberry-like masses are seen both upon the nerve head and in the outlying fundus This plate is taken from Lawson's case, reported in the Transactions of the Ophthalmological Society of the United Kingdom, vol III The second from Nettleship's case, vol IV of the Transactions of the Ophthalmological Society of the United Kingdom, shows the other variety, in which the lesions are small yellowish dots, showing a tendency to group in large numbers in the central region of the eye ground This picture, is a very faithful delineation of a variety of colloid change, which Tay, and afterward Nettleship, designated “guttate choroiditis ” The term “verrucosités hyalines’ had also been applied to this affection by French writers (Terson) Many original articles have appeared on the subject in ophthalmologic literature, among which that of A Terson (*Arch d Ophthalmologie*, No 6, 1892,) contains a complete bibliography and a very thorough resumé of the anatomic and histologic points involved In all the reports, the fact seems to be established that these lesions are simply senile degenerative changes, or, if seen in adult life, they accompany severe intra ocular disease

There seems to be no excuse for the various names under which this affection has been described There are no evidences of choroidal inflammation, but simply a retrograde change in the lamina vitrea choroidea, and hence the use of the word choroiditis is inadvisable Colloid degeneration has been found occurring in the cartilages of old people, and according to Fuchs, the arcus senilis is produced by colloid changes in the periphery of the cornea The most satisfactory term for this affection would seem to be “colloid changes in the choroid ” The hyalin masses on the nerve-head, or drusen, of which I reported cases in the *International Medical Magazine*, November, 1893, have been regarded until recently as identical with colloid choroidal lesions Hirschberg, (*Centralbl fur prakt Augenheilk*, June and July, 1891) after extensive study of post-mortem specimens with different chemic reagents (for the details of which consult his article) advanced the opinion that these were two separate diseases His position was strengthened by the very thorough post-mortem study of de Schweinitz, reported in the Transactions of the American Ophthalmological Society for 1892 He also believed them to be distinct affections From the clinical as well as ophthalmoscopic standpoint, however, these lesions appear to be identical In this article I report a case, with rough but accurate drawing of the fundus, in which typical drusen and colloid changes of the choroid are associated in the same eye ground There are many difficult points in arriving at a decision that will reconcile all the conditions present

There is still considerable doubt among anatomists regarding the exact anatomic relation of the sclera and choroid at the lamina cribrosa It has been denied that the lamina vitrea choroidea is found in this situation and hence the impossibility of these colloid masses, on the nerve head, springing from the lamina vitrea, has been insisted upon Again, there are conflicting views as regards the origin of the colloid changes in the choroid By some they are regarded as of epithelial origin, by others it is claimed that the intercellular tissue of the lamina vitrea breaks down and forms colloid degeneration Without attempting to reconcile the views advanced by different observers, the subject viewed from a clinical standpoint would seem to show the identity of drusen and these colloid changes Patients suffering from choroidal disease affecting circumscribed areas, rarely consult the ophthalmologist on account of symptoms directly referable to the choroidal lesions With the ophthalmoscope, the yellowish or whitish spots, often heavily pigmented and scattered over the eye ground, constitute the familiar picture of choroiditis It is in the associated retinal involvement, and that, too when the more central portions of the eye ground are diseased, that reduced vision, lowered light sense, metamorphosia, photopsia or scotoma form part of the clinical picture of choroiditis True it is, moreover, that these associated retinal changes are the rule in inflammation of the choroid In colloid changes of the choroid, although the ophthalmoscopic appearances are startling and the masses occupy the macular region, over an extensive area, at no time in the clinical history of the disease is the functional activity of the retina interfered with From ophthalmoscopic examination, the observer would expect to find a large central scotoma interfering with the use of the eye and producing marked visual defect On the contrary, sharpness of sight remains unaffected and there is not even a reduction in the light-sense as tested by lowering the illumination upon the test letters

There are two distinct clinical groups which have as their distinguishing features the size of the separate globular formations and the character of their arrangement in the fundus In the first group, corresponding to "guttate choroiditis," the affection occurs as separate, small, yellowish dots, often no larger than the diameter of a retinal vein, showing a marked tendency to invade the macular region where they are often so numerous that an appearance of heaping is produced At times, however, the picture is not unlike an atypical form of albuminuric retinitis

In the second group we have large globular acinous formations similar in appearance to drusen and as in that affection, occupying symmetrical positions in both eye-grounds Each globular mass may have a diameter equivalent to three or four times the size of a retinal vein

In connection with this paper, three cases presenting all the features of this rare and interesting disease are reported Before relating the clinical histories, I wish to call attention to the fact that these colloid changes when sought with the ophthalmoscope, appear much more pronounced under lowered illumination When examined under the enlarged image of the direct method with lowered illumination, the observer frequently changing the direction in which the light strikes the fundus by moving the mirror from side to side, these translucent masses seem to be thrown into relief against the background of the fundus and their true size and appearance can then be best appreciated In presenting the following clinical histories only the more characteristic in the two groups have been selected Among the distinguishing features, from a general standpoint, my experience has been that the colloid changes in group one, have invariably been seen in patients past middle life, the average age being from 60 to 70 Whether it is simply a coincidence or not, rheumatism of a severe chronic type, often with articular changes, was seen in nearly every patient of this group In one exception to this rule in which the small, yellowish colloid dots filled the macular region in a patient aged 28, there were all the evidences of marked gouty diathesis It is worthy of note that both gout and rheumatism, as well as Bright's disease, were frequently found associated with drusen (Gurwitch)

Case 1 —Miss F , aged 63, a sufferer from chronic rheumatism, with sclerotic changes in the arteries, consulted me for presbyopic trouble The entire fundus showed small yellowish spots more numerous in the macular region, choroidal in situation, and symmetrically placed in each eye Her corrected vision was 6–6 Examination of the urine gave negative results Two years later, the vision and fundus condition remained the same The ophthalmoscopic picture suggests albuminuric retinitis

Case 2 —Daniel F , aged 70, *was seen Dec 11, 1893* He sought advice because of inability to use his eyes at the near point The case is important as showing both large and small *globular yellowish* masses in the same eye In the right eye the ophthalmoscope showed in the temporal region around the macula lutea, an area composed of large and small colloid changes in the choroid The largest of these masses showed a diameter equivalent to four times the diameter of a large retinal vein There were *no secondary* retinal changes H=1D In the left eye, the small yellowish dots were seen scattered more generally throughout the fundus, as well *as grouped in the macular region*, but no large masses were discovered With +1 00 D⊃+1 00 cyl ax ; 90° corrected vision was 6–6 Urine examined and found negative

Under the second group, I shall report more in detail the clinical histories of three patients in whom the colloid changes were startling in appearance, covering *extensive portions of the central region* in both eyes, and occurring in patients of early adult life In one case there was *pulmonary tuberculosis*, in another chronic interstitial nephritis, and in the last, a marked gouty diathesis

Case 1 —Mrs S , aged 36, (whose fundus appearances are shown in water-colored sketch) consulted me on April 22, 1893, suffering from accommodative and muscular asthenopia She was extremely neurasthenic, and the ophthalmoscopic examination *was difficult on account of marked* retinal hyperesthesia Her appearance suggested pulmonary phthisis, and she stated that three years ago she was examined *and that the* sputum showed bacilli After spending a year and a half in a warm dry climate she had returned apparently cured of pulmonary disease In the right eye vision 6–12 , in left eye 6–12 She read type D 0 50 to 17 centimeters At 6 meters, there was esophoria of 18° At 30 centimeters 14° She had been suffering from severe headache and weak eyes, complained of diplopia after reading or sewing, and nausea and vomiting followed prolonged use of the eyes *at close work The ophthalmoscope* revealed in the macular region of each eye an area horizontally oval 3 + 2 disk diameters, composed of globular, yellowish, mulberry-like masses over which the retinal vessels passed with some slight elevation There were no evidences of secondary retinal changes The lesion closely simulated drusen Careful examination of the entire fundus showed occasional small yellowish dots but no large masses such as were seen in the macular region An interesting fact was the high degree of esophoria, present, and the opinion was advanced by Dr S D Risley, who saw the case, that the macular condition *might account for the muscular defect* The diagnosis lay between tubercular disease which was favored by the general condition of the patient, and colloid changes in the lamina vitrea choroidea Her corrected vision was 6–7½ in each eye, and the field of vision was normal A year later when I tenotomized both interni with marked benefit to the patient, the vision rose to 6–6 Dr de Schweinitz saw the patient and at that time spoke of its marked resemblance to a case which he has since reported with a water-color sketch of the fundus, in last year's Transactions of the American Ophthalmological Society

Case 2 —Mrs R , aged 40, was referred *to me* by Dr H A Slocum for examination of the fundus There was chronic interstitial nephritis, and some disturbance of vision, more marked in the left eye, led him to refer the case to me to determine whether the refractive error or a retinal lesion were responsible for the visual defect Her right vision was 6–6 , left vision 6–9 The ophthalmoscopic examination in the right eye showed simple congestion of the nerve head with soft blurring of its edges H. = 2 or 3 D In the macular region an extensive area three times the size of the disk was covered with characteristic colloid acinous formations. There was in this eye some *choroidal* atrophy which was much more marked in the left though there were no retinal changes Careful correction of the refractive error of the left eye failed to improve the vision beyond *6–9 There were* no typical retinal conditions suggestive of Bright's disease. The water-color sketch of the previous case would almost apply to this fundus

Case 3 in this interesting group, is that of Mr H , aged 38, who consulted me on Sept 17, 1894, on account of accommodative asthenopia Both eye grounds showed the most remarkable condition of colloid changes that I have ever seen Mr H was a man of slight build nervous temperament, of strong gouty tendency, whose urine showed an excessive amount of uric acid with high specific gravity Syphilis and tuberculosis can be absolutely eliminated from the history after a careful study With his hypermetropic astigmatism corrected, his vision was 6–6 in each eye The fundus presented the following remarkable characteristics the entire choroid was occupied by numerous disk-shaped areas, three or four times the diameter of a retinal vein, yellowish in the center with lace like delicate pigmentation of retinal and choroidal situation The entire fundus being occupied by these colloid changes gave an ophthalmoscopic picture simulating disseminated choroiditis In fact the diagnosis from disseminated choroiditis in this case was one of considerable difficulty The absence of any important retinal, optic nerve and vitreous involvement, was strictly in favor of the colloid nature of the lesion as opposed to its being an inflammatory disease of the choroid Careful examination of his field of vision showed no defect and there was absolutely no reduction in a light sense Dr de Schweinitz who also saw this case, was of opinion that it was colloid degeneration of the choroid, with secondary pigment disturbance without involvement of the important retinal layers The lesion was perhaps congenital or at least of infant origin At his suggestion I examined other members of Mr H's family without finding a similar choroidal lesion on either side, although the family record was poor, there being several cases of glaucoma among maternal aunts At the present day the vision remains normal and the fundus appearance has not changed

Case 4—The last case to which I desire to call attention is one presenting choroidal changes of colloid nature together with extensive denser formation of the nerve head, which is almost concealed by thickly packed globular masses The fundus appearances in this patient aged 59, whose corrected vision was 6–6 are shown in my rough drawing

In conclusion, certain points in the study of this choroidal affection impressed me as being worthy of summarizing 1, the entire absence of any visual defect resulting from even the most striking ophthalmoscopic changes, 2, the almost constant relation between senility and the multiple small colloid masses seen in group one, and the absence of any such relation in the large globular masses of group two, 3 the almost invariable situation of the lesion in the central or macular region and the symmetry of arrangement in each eye, 4, the importance while studying the fundus of using a low power of illumination and of continually changing the direction of the light from the ophthalmoscopic mirror in order to reveal the true outlines of these masses, 5, the clinical proof of the identity of drusen with these extensive colloid changes, both from the standpoint of symptomatology as well as from the fact that in at least one case, drusen and colloid changes of the choroid existed in the same eye, 6, and lastly, the importance of diagnosing this colloid change of the choroid from exudative choroiditis, tubercular disease of the choroid and in some instances from albuminuric retinitis of the macular region

108 S 18th Street

DISCUSSION

Dr G de Schweinitz, Philadelphia—As you know, I have had the opportunity of studying microscopically the so-called drüsen in the nerve head and, clinically several cases of choroidal diseases resembling these hyalin bodies in the papilla Thus far, at least, it is not proved that the drüsen and the colloid bodies springing from the lamina vitrea, are identically pathologic processes Moreover we are not in possession of the information which decides what relation these so-called colloid choroidal changes which I have figured and which Dr Carpenter so well described this morning bear to the other two lesions, viz, drüsen and colloid bodies from the lamina Therefore I am doubtful whether all of these cases should be grouped together, although I am sure we should all agree with Dr Carpenter that they constitute a class of cases to be separated from inflammatory disease My experience with guttate changes is that they always produce defective central vision and negative scotoma, while these colloid macular changes in young people are not connected with defective central vision indeed, even the light sense is perfect Drüsen may be seen in otherwise normal nerve heads or in one that is atrophied, therefore they may be associated, with or without visual disturbance Symmetrical disposition of the drusen is not universal I have reported one monolateral case and studied another Dr Gifford, I know, is now studying a similar unilateral case On the other hand, the colloid changes in the choroid, in my experience, are always symmetrical Dr Carpenter's cautions in regard to the best method of studying these lesions are timely

Dr B Alexander Randall, Philadelphia—Several pathologic conditions are comprised in these "colloid" appearances as many of us have doubtless seen, colloid degeneration of the retinal pigment epithelium, colloid deposits in the choroidal stroma, and similar lesions in the retina akin to the mere serous vacuolization that is so commonly seen at the periphery In a considerable group of clinical cases it has seemed impossible often to discriminate which process was present in the ophthalmoscopic picture

Dr Harold Gifford, Omaha, Neb—I have followed some cases of this disease for several years One case occurred in a girl 9 years of age with a very remarkable change in the optic nerve This case I report as an exception, in that the sight was entirely destroyed The retinal arteries were obliterated, whether as the result of colloid changes or of some other disease I am uncertain One point you should consider is, What sort of prognosis are you going to give? Will they retain what vision they have through life? I have had a case in which sight was reduced to 20–50 by these changes, that is, I could find no other cause for the reduced vision

Dr Herman Knapp, New York—I wish to acknowledge the value of Dr Friedenwald's paper The subject of hemorrhages in the background of the eye is larger and more important than we formerly thought Many of the varied appearances of striation and white or black deposits which were formerly complained of can now be referred to previous hemorrhages after we have had time to watch a large number of cases where the gradual conversion of the blood into these conditions could be followed up As to the clinical course of the colloid excrescences of the choroid I have the advantage of age over most of you, in stating that for years they can remain in *statu quo* In a gentleman whose eyes had extensive colloid deposits in the choroid, they have not notably changed these twenty years Regarding the differential diagnosis, these excrescences may be mistaken for a disseminate choroiditis as it occurs in syphilis In the latter disease the small patches have a somewhat notched border beset with pigment (as the colloid occasionally are too) and their color is white, the white of the sclerotic, whereas the colloid deposits look dull white like old ivory

Dr J T Carpenter Jr Philadelphia—I am glad to hear from others that the question of diagnosis between disseminated choroiditis and some cases of extensive colloid choroidal degeneration has been one of some difficulty The grouping of these cases was done simply from a clinical standpoint The prognosis is invariably good as regards vision, and Dr Gifford's cases must have been of serious optic nerve lesion, probably posterior to the papilla

THE TECHNIQUE OF TENOTOMY OF THE OCULAR MUSCLES

Read in the Section on Ophthalmology, at the Forty sixth Annual *Meeting of the American Medical Association*
Baltimore Md, May 7 10 1895

BY LEARTUS CONNOR, A M, M D
DETROIT MICH

It is desirable that both patient and operator be in good physical condition The surgeon, his assistant, patient, instruments, and operating room should all be rendered as aseptic as possible, because asepsis is the fundamental principle of modern surgery, which no ophthalmologist can afford to disregard, even when doing an ocular tenotomy The operator's hands should be washed with pure soap and hot water, by the aid of a hand brush, so as to loosen all bacteria and other infectious materials lodged on the skin, attached to the hairs, embedded in the mouths of the oil or sweat glands or under the finger nails This loosened *débris* is best removed by running hot water The face, and beard (if the operator have one), are cleansed with scrupulous care When dried, the hands are soaked in bichlorid solution, 1 to 1000 The assistant and patient cleanse themselves in a similar manner Especial care is taken to free from all septic material the edges of the eyelids, lacrymal passages and conjunctiva by washing with the bichlorid solution The instruments are to be sterilized in steam or boiling water, and just before using, soaked in absolute alcohol, dried and laid upon an aseptic tray The room freed from all infection should afford adequate light, as the best work is impossible unless the surgeon can see distinctly each step

An anesthetic, local or general, is imperative Usually cocain suffices, but occasionally the patient is so uncontrollable as to compel the administration of a general anesthetic—ether, chloroform or methylene bichlorid The surgeon's personal views, determines his selection of the anesthetic Unquestionably, chloroform is more dangerous, but it is more pleasant to both patient and operator, and I do not recall a death from an ocular tenotomy done under its influence The instruments needed are a speculum, lid retractor, fixation forceps, fine toothed forceps, a blunt pointed scissors curved on the flat, tenotomy hooks, fine needles and fine silk sutures, sterilized absorbent cotton and bandage

The several steps of the operation are 1, the opening of the conjunctiva, 2, opening the capsule of Tenon, 3, lifting the tendon from its sheath, 4, division of the tendon, 5, dressing of the wound It is improbable that any operator takes these steps exactly as any other, but all open the conjunctiva and capsule, divide the tendon and dress the wound in some manner Some open the conjunctiva and capsule at the lower edge of the tendon and parallel to its fibers, some at the center of the tendon and in the same direction, some at right angles to the tendon fibers, either at their outer edge, at their center or along the entire line of their insertion, some make the opening large, others of medium size, and others small Some divide the tendon subconjunctivally, others partially so, and others openly Some unite the edges of the conjunctiva with fine silk suture, others leave the wound entirely open Some use forceps to lift the tendon for division by the scissors, others use the blunt hook of various shapes, all however use either forceps or blunt hook Doubtless each surgeon, by more or less unconscious experiment, finds the method suited to his personal equation and adopts it, as giving him the best results The end sought is the division of the tendon close to its insertion, without unduly disturbing the adjacent tissues

Some surgeons dress the wound by putting a few drops of boric acid solution into the conjunctival cul-de sac, then a bit of linen moistened in bichlorid solution on the closed lids, then a bit of borated cotton and, finally, a bandage over all, others after cleansing the conjunctiva, simply close the lids with isinglass adhesive plaster, others leave the eye entirely open, after the effects of the cocain have disappeared, others protect the eye from light, dust and wind with a blind, and have the eye soaked in hot water at regular intervals, to hasten repair and relieve discomfort Good results attend any of these variations in operating or dressing, at the hands of a skillful operator While unable to discuss their merits or demerits, the open dressing commends itself because it best utilizes the vision of the squinting eye in fixing the eyes in the best position while re-attachment of the divided tendon is taking place If the operation be done aseptically the wound should be carefully closed by suture, unless from its small size and horizontal direction there is no necessity to exclude air after the effects of the cocain have disappeared

In estimating the effects of a tenotomy we must consider the weakened power of the muscle operated upon, the muscular force of its antagonist, and the elasticity of the tissues—factors which vary greatly in individual cases Roughly, the force of the muscles can be determined by the degrees to which they are able to turn the eye in the direction of their long axes, during their greatest contraction This motility affords a sound guide in estimating the effects of a tenotomy Thus, if the motility of the muscles be unchanged, clearly the operation is ineffective and the cause must be searched for and removed

To operate intelligently, the surgeon must, first, measure the extent of the strabismus, and to know his results he must repeat his measurement after the tenotomy The best means for making such measurements are the use of prisms, producing double images at 6 or 7 meters The difficulty with this method, lies in the fact that not all squint eyes possess sufficient vision to render it available Such cases compel the surgeon to select a method applicable to them The varieties of these are legion Some operators depend entirely upon their own eyes, both in measuring the amount of squint, and the perfection of its correction Others mark with an ink dot the position of the center of the pupil or edge of the cornea of the squinting eye, on the edge of the eyelid, both in the squinting and fixing position—the space between the two dots roughly measuring the deviation The strabismometer, with others takes the place of the ink dots In Graefe's method, the flame of a candle is fixed by the squinting eye at a distance of 5 meters, and the zero point of the scale brought beneath the corneal image of the flame Then the fixing eye is arranged for the same flame, and we note how far from the middle of the pupil the squinting eye has deviated from zero The observer should be in the visual axis of the squinting eye, while making his observation The secondary variation of the fixing eye is measured in the same manner Of the many other methods, by perimeters, tapes, boards, etc, we can not speak

In my own work, the following technique has proved satisfactory the vision of each eye is carefully noted, all ametropia, ascertained under atropin, fully noted, if such correction will diminish the strain upon the weaker muscles, The power of the several muscles is measured, all defects being accurately recorded The method of ascertaining the amount of squint is selected according to the character of the case, always when possible utilizing prisms The operation is planned, so that there will remain a slight convergence immediately after the tenotomy of the interni or externi, but in vertical squint I aim to undercorrect In all cases it is sought to secure such motility of the muscles as will so obviate their defects as to enable them to center the visual lines upon an object within the fields of vision The accomplishment of this frequently calls for the division of the operation between the muscles of the two eyes, even though an operation on one might make the eyes straight The instruments used are a pair of scissors, curved on the flat, both points blunt, blades narrowed near their ends, firm enough to divide the tendon without springing, and so nicely adjusted as to cut the tissues to their very ends The forceps are delicate, yet sufficiently strong, that they readily grasp and hold firmly the tendon The blunt hook is curved nearly at a right angle and quite small, as it is used to lift but half of the tendon at once, because I operate from the center toward either side The speculum and lid retractor are unimportant, if only they afford an unobstructed view of the field of operation, and cause the patient a minimum of discomfort The lid retractor in the hands of a good assistant, is especially convenient when operating upon the superior or inferior recti

The fixation forceps is rarely called for, except in cases requiring a general anesthetic, because under cocain the patient is able to hold the eyeball in the correct position These instruments are sterilized, dried, soaked in absolute alcohol, wiped and placed on a clean tray just before using

The patient lies in a half reclining chair, facing a good light, with head wrapped in towel moistened in bichlorid solution, and clothes covered with a clean apron to the neck The operator, assistant and patient have been rendered aseptic by the method described

The cocain solution, 4 per cent, made with distilled water and 16 grains of boric acid to the ounce, is dropped in the cul-de sac of the eye to be tenotomized, repeated every few moments till the conjunctiva has become insensible, and during the several stages of the operation, as the case demands

The assistant steadies the patient's head, prepared to remove with absorbent cotton any hemorrhage which may obstruct the field of operation

In tenotomy of the internus, the operator sits or stands, facing the patient, who is directed to turn the eyeball strongly outward, the conjunctiva is seized with the forceps, so as to make a small vertical fold, directly over the insertion of the tendon With the scissors this fold is divided, making a short horizontal opening of the conjunctiva Through this opening the forceps grasp the tendon sheath forming a vertical fold similar to that made in the conjunctiva, this fold is divided, thus laying bare the tendon, which is seized by the forceps so as to make a horizontal fold, and by slight traction from the eyeball, exhibits its insertion The division of this fold close to the sclerotic, by the scissors, makes a central opening into the tendon The fibers on either side are now severed, by placing one blade of the scissors beneath, and one above the tendon but below the conjunctiva, and closing the blades one or more times as may be needed Usually this can be done completely by the scissors alone, but if it fails, the little blunt hook is made to enter the wound in such a manner as to catch stray attachments, and permit their division with the scissors The motility of the eye outward is now examined, if it equals that of the other eye, enough has been done, but if it retain the same motility as before the operation, then the occasion needs to be sought and removed The behavior of the eyes when fixed upon an object at one-sixth of a meter or less is important, if they diverge, we know that the effect is too great and must be limited by suture If they converge as before the operation, the tenotomy has been imperfect, but if the eyes remain steady or slightly converged, the result will be satisfactory, or, still more certainly, if, when tested by prisms, at 6 meters, the eyes maintain a condition of vertical equilibrium—the misplaced arc of movement of the squinting eye has been replaced in its normal position

But if the tenotomy has failed to adequately reduce the convergence, we have several courses of procedure, doing of a tenotomy on the other eye, severing more or less freely the attachments of the muscle or muscles, the use of sutures, advancement of the weaker muscle, or increasing the relative power of the defective muscles as in insufficiencies In convergent squint I have never had occasion to use a suture to increase the effect of the tenotomy In tenotomy of the externus, the eyeball is turned strongly inward in the horizontal meridian, the conjunctiva grasped by the forceps at about 7 millimeters from the external border of the cornea and the other steps taken as when operating upon the internus About 2 degrees may be gained by a simple tenotomy of the externus, though this is uncertain and likely to diminish after a time The use of sutures from the superficial fibers of the sclerotic, at the inner sclerocorneal junction, to the inner commissure, will enable the surgeon to greatly increase this effect If both eyes be tenotomized, the sutures may be tied over the bridge of the nose, and the divided ends of the tendons made to unite with the sclerotic as far back as desired I prefer the advancement of the weaker muscle to the use of sutures in divergent squint

In tenotomy of the superior rectus, the eyeball is turned downward as far as possible, so as to bring its insertion fully in view The assistant by a lid retractor lifts the upper lid, the conjunctiva is opened at about 8 millimeters from the corneal margin, and the further steps taken as in the other tendons The insertion of this tendon is near that of the superior oblique, and slants outward and backward, points worthy of remembrance during the tenotomy Tenotomy of the inferior rectus is done in the same manner as that of the other tendons, the insertion being about 7 millimeters from the corneal margin

After each operation the position of the eyes, and the motility of the muscles are carefully studied, so that if the effect be insufficient it may be increased by some available method, or if it be too great it may be restricted

The opening into the conjunctiva is so small and so located that it usually closes sufficiently without suture The conjunctival cul de sac is cleansed with boric acid solution, the eye protected from light by a shade until the effects of the cocain have passed away, and then left open The patient is directed to soak the eye in very hot water frequently, to relieve discomfort and promote repair of the wound

An ocular tenotomy, done after the manner described, is nearly painless and bloodless, absolutely free from any danger, involves the least traumatism, gives very definite results requires no after dressing, and secures binocular vision, if this be possible by a tenotomy

THE SLIGHT EFFECT SOMETIMES OBTAINED AS THE RESULT OF FREE TENOTOMIES OF THE OCULAR MUSCLES FOR HETEROPHORIA

Read in the Section on Ophthalmology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7 10 1895

BY SAMUEL THEOBALD, M D

OPHTHALMIC AND AURAL SURGEON TO THE JOHNS HOPKINS HOSPITAL, AND TO THE BALTIMORE EYE EAR AND THROAT CHARITY HOSPITAL

BALTIMORE

I believe it is a generally recognized fact that in operations upon the external eye muscles for the correction of heterophoria or of strabismus, a given amount of "tenotomizing"—if one may use this convenient, but, perhaps, not altogether legitimate word—is by no means always followed by a corresponding and definite amount of correction The same degree of section of the muscle and capsule in one case produces a marked effect, while in another, the result of a precisely similar operation is comparatively slight No comprehensive and satisfactory explanation of this fact, so far as I am aware, has yet been offered, and I think it may be safely asserted that even the most experienced operator can not say with any assurance, in advance of a tenotomy, just what the effect of a given amount of cutting will be

As a general principle, it may be asserted that the result of a tenotomy upon an ocular muscle will depend upon the extent to which the muscle's attachment to the sclerotic is set back If the divided tendon re attaches itself to the sclerotic, without slipping back—at the point of its previous attachment—the effect will be almost or quite *nil*, on the other hand, if it slips back considerably, the effect will be marked In accordance with this generally recognized rule, when one wishes to obtain a decided effect from a tenotomy one does not limit the section to the tendon, but divides more or less freely Tenon's capsule, which permits a wider recession of the muscle, while, if a slight effect is desired, one includes in the section only the tendon proper To this extent the effect of our operations is under control, but the fact still remains that the result of a given amount of cutting varies very greatly in different individuals While, as has been said, we do not fully understand the reason of this, the matter is one as to which we are, at all events, not wholly in the dark

It may be safely affirmed, I think, that, other things being equal, the smaller an eyeball is, and, perhaps, the more deeply seated it is in the orbit, the less will be the effect of the division of one of its muscles, the larger the ball and the more prominent its position, the greater will be the effect Hence it follows that, as a rule, a tenotomy upon a hypermetropic eye may be expected to produce a less marked result than a similar operation upon a myopic eye The explanation being that in the larger, and more prominent myopic eye the tendon recedes to a greater extent before becoming re-attached than it does in the smaller, and less prominent, hypermetropic eye

My experience inclines me to the belief also that, usually, a tenotomy performed for the correction of an actual squint produces a relatively greater effect upon the muscular balance of the eyes than does one performed for the relief of heterophoria, and here, again, it is probably a question of the extent of the recession of the divided muscle, for this, it would seem, is likely to be greater in the case of the contracted muscle of squint, than in the muscle of normal length with which we have to do in heterophoria

The comparative size of the muscle operated upon, whether a thick, well developed muscle or the reverse, has also seemed to me to have an influence upon the result For example, a tenotomy performed upon a slender internal rectus muscle, which has only been able to develop a convergent squint of intermittent character, will produce a more decided effect than one upon a well developed muscle, such as is usually found in the fixed type of convergent strabismus

It seems probable, too, for some reason that we do not yet understand, that the muscles of certain eyes, when separated from the sclerotic, have a greater disposition to retract toward their orbital attachment than the corresponding muscles of other eyes, and this would tend to increase the effect of their division The thickness and strength of Tenon's capsule, which doubtless vary in different individuals, would also probably exert an influence upon the recession of the muscle and hence upon the effect of the tenotomy

While in strabismus we usually expect a better and more decided result from a tenotomy performed upon the internal rectus than from one done upon the external rectus, the striking instances of slight effect following free tenotomies for heterophoria which I have met with, have invariably occurred in operations upon the internal recti for esophoria

In order not to consume the time of the Section, I shall describe briefly only two of the most striking of the cases of this character which I have encountered, but I may state that I have the records of others which almost parallel them

Case 1—Miss P a school girl, about 16 years of age, was brought to me in November, 1893, for the relief of asthenopia The ophthalmoscope revealed only a slight amount of hypermetropia, but showed marked negative symmetrical aberration of both eyes By the vertical diplopia test there was esophoria at 20′ of 11°, at 13″ of 8½° A later examination, a few days subsequently, gave, however by the same test, only 7½° of esophoria at 20′, and 7° at 13″ A mydriatic was used (hyoscymia hydrobromate) and revealed hardly 75 D of hypermetropia Under its influence there seemed to be a little astigmatism according to the rule, but this finding was not confirmed after the effect of the mydriatic disappeared With paralyzed accommodation, the esophoria at 20′ was 10½°

On Dec 8, 1893, the vertical diplopia test having previously shown esophoria at 20′=9°, I did, as my notes state, a "pretty free tenotomy" of the L internal rectus Two days afterward there was esophoria at 20′=1°, with orthophoria at 13″ May 3, 1894, with L eye + 50s, R eye + 37s, there was esophoria at 20′ varying from 9° to 11° At this time I prescribed glasses for constant wear as follows

L eye ⊃ 50s Prism 3° base out
R eye ⊃ 37s Prism 3° base out

May 19, the vertical diplopia test gave, with these glasses on, additional esophoria at 20′ of 10°, *i e*, a total of 16° I then did "a free tenotomy" of the R internal rectus, dividing Tenon's capsule "almost as freely as for squint," as noted at the time in my record of the case Two days afterward, without correcting glasses, I found esophoria at 20′=7°, at 13″=4° A few weeks later there was esophoria at 20′=11°

The last examination of the muscular balance was made Oct 31, 1894, and showed, by the vertical diplopia test, with full correction of the manifest hypermetropia, esophoria at 20′=9° Thus it will be seen that in this case a free tenotomy was performed upon each internal rectus (one of them involving a liberal division of the capsule) without appreciably reducing the original esophoria, for, it will be remembered that the esophoria at the first examination varied in amount from 11° to 7½° at 20′

Case 2—Mr W, aged 26, artist, consulted me on account of asthenopia, in July, 1890 He was wearing at the time for each eye + 50c 90′ Without correcting glasses the vertical diplopia test showed esophoria at 20′=10½°, at 13″=8° There was no hyperphoria The ophthalmoscope showed less than 1 D of hypermetropia, and this was subsequently confirmed by the use of a mydriatic (a 2 grain solution of duboisia) A later test, with full correction of the astigmatism and manifest hypermetropia, showed esophoria at 20′=9½°, at 13″=8°

July 24, 1890, I divided the L internal rectus "completely" Two days later there was esophoria at 20′=10¾°, at 13″=7° July 31 esophoria at 20′=11½°, at 13″=7°, adduction at 20′ =35°, abduction =8° August 2, I did a free tenotomy" of the R internal rectus, "*dividing the outlying fibers of Tenon's capsule*" Two days later there was still esophoria at 20′ =8°, at 13″=6½° to 7° October 14, with the glasses prescribed for the correction of his manifest error of refraction, there was esophoria at 20′=6°, at 13″=2° Without correcting glasses there was esophoria at 20′=7°, at 13″=4° At 20′ there was adduction =46°, abduction =10° March 12 1891, with his correcting glasses, there was esophoria at 20′=7½° to 8°, at 13″=4°, no hyperphoria As the result of gymnastic exercises with prisms there was, subsequently, a reduction of the esophoria of about 2½°, which, however, was probably *not* permanent In this case, as will be seen by a comparison of the tests made with correction of the *manifest refractive error before and after the operations*, there was, as the result of two free tenotomies (such as would have sufficed, in many cases, for the correction of a decided strabismus) a lessening of the esophoria at 20′ of scarcely 2°, and at 13″ of only 4°

Before concluding, it may be well to mention the *manner* in which the tenotomies were performed in these cases and in other similar cases which I have met with Before the introduction of cocain it was my habit to perform all tenotomies subconjunctivally, but, I soon found that with the eye under cocain this operation was not so easy of performance, because of the tightening effect of the cocain upon the conjunctiva I, therefore, abandoned this method and adopted the "button-hole" operation, which I have since employed in all cases In performing this operation, I make a longitudinal incision through the conjunctiva directly over the attachment of the muscle, and then free the conjunctiva from the underlying tissue Next, I seize the tendon with forceps, and divide it just at its point of attachment to the sclerotic After the tendon proper has been divided, I introduce my crochet-pointed strabismus hook through the opening thus made and extend the incision upward and downward, dividing, more or less freely, as may be indicated, the lateral fibers of the tendon and Tenon's capsule This was, then, the method in which the *tenotomies* were performed in the cases which I have related

THE LIMITATIONS OF TENOTOMY OF THE EYE MUSCLES

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10, 1895

BY HOWARD F HANSELL, A.M , M D

CLINICAL PROFESSOR OF OPHTHALMOLOGY JEFFERSON MEDICAL COLLEGE
ADJUNCT PROFESSOR OF DISEASES OF THE EYE PHILADELPHIA
POLYCLINIC CONSULTING OPHTHALMOLOGIST CHESTER
COUNTY HOSPITAL
PHILADELPHIA

If we assume parallelism of the visual lines to be the functional position of rest, maintained by unconscious innervation and divergence the anatomic position of rest (Hansen-Grut), orthophoria or equilibrium for far and near is a condition of adjustment or relatively equal tension or balance of nerve and muscular force, and is not in any sense a condition of repose or relaxation of the muscles as in sleep or in ether narcosis

Heterophoria and Heterotropia, tendencies to deviation or deviations, are the result of spasm or supranormal contraction of a muscle or set of muscles, or of weakness or insufficiency of their antagonists

In this paper I will consider, very briefly, the abnormal relations of the visual axes, non-paralytic in origin, and the operative methods which theory and practice seem to demand for their adjustment

1 *Esotropia or Internal Strabismus*—Hypermetropia is the cause in 75 to 90 per cent of all cases The squint is manifest and "active" and depends upon the relation of accommodation and convergence In recent cases the contraction of the internus is excessive and the abduction is of normal strength In ancient cases the muscular structure has undergone molecular change and abduction has become weakened

(*a*) *Concomitant or Alternating Squint*, fixation with either eye, the vision practically the same in each *Amblyopia is necessarily precluded* The deviation is upward and inward, the latter manifest, the former easily demonstrated by the relatively lower position of the false image The obliquity of the squinting eye is convincing evidence of the associated and responsive action of the external muscles supplied by the third nerve to the stimulation of the accommodation, but it has no bearing on the result of treatment directed to the interni, since the upward deviation is transferred with the inward, when fixation is transferred, and since both eyes functionate, though not simultaneously, neither external rectus undergoes *degeneration or indeed loses any of* its abducting power When the prolonged paralysis of accommodation followed by full correction of hypermetropia worn for a sufficiently long time have proved inefficacious, tenotomy of each internal rectus, dividing the operation equally between the two muscles, and without advancement of either externus, is the proper surgical procedure The effect of the operation can be readily determined by the approximation of the false and true images, and when finally they have fused, the desire for binocular fixation or of fusion will maintain them single

(*b*) *Constant Monocular Squint*, one and the same eye always used in fixation, the squinting eye amblyopic The cornea of the amblyopic eye is turned inward and upward, owing to the combined action of the extrinsic muscles under the control of the third nerve Outward rotation is limited The external rectus is deficient in power and innervation, the muscle itself having become flabby, stretched and incapable of normal function Tenotomy of either or both internal muscles is unavailing, without advancement of the external of the squinting eye In addition, section of the superior of the same eye is often necessary The operation, sometimes practiced, of extensively dividing the internus together with its lateral attachments, thus practically paralyzing the muscle, gives a temporary cosmetic improvement but is to be deprecated, since that eye in the course of a few months or a year will become divergent We can rarely, if ever, in these cases restore the function of the squinting eye, and our operations may be the cause of annoying diplopia

2 *Exotropia, or Divergent Strabismus*—The common causes of external squint are loss of convergence through deficient innervation or muscular weakness, and loss of convergence from mechanic and anatomic obstacles to adduction The former

is found in those cases which arise independently of refractive error and can not be ascribed to it, in patients convalescing from exhausting illnesses, in neurotics or those who suffer from accommodative asthenopia from low degrees of heterophoria and astigmatism and whose general muscular and nervous system is responsive to slight abnormalities. It is seldom due to absolute supra normal strength of the externi but innervational weakness of the interni, not a loss of muscular power of each internus, for the balls are susceptible of full rotation but a loss of convergence, probably of central origin.

In order to effect a cure, adduction must be raised to the normal standard. The innervation may be increased, I believe by nerve tonics, such as nux vomica and the muscular contractile power by prism exercise, but these means are unavailing and a waste of time unless binocular vision is present, at least in part. Surgical interference is necessary and we have an apparent choice of three procedures—tenotomy, advancement, or a combination of both. Tenotomy is objectionable since we are destroying instead of building up, weakening a normal set of muscles to a degree to correspond to an abnormal weakness of the antagonists, limiting abduction and perhaps giving crossed diplopia for near, and homonymous diplopia for far, and never restore equilibrium.

The mechanical and anatomic obstacles to convergence are the increased length of the eyeball in myopia and the divergence of the orbits and the upper and outward position of the eyes in utter relaxation of the muscles as in sleep. The divergence of myopia is passive and chronic and follows the inability of the interni, unstimulated by and unassociated with accommodative effort, to converge the lengthened balls. Tenotomy alone is useless. Correction of the myopia, demanding the use of the accommodation on near work, prism exercise and advancement of the interni are sometimes effective. Careful inquiry into the history of cases of divergent squint will sometimes develop the interesting fact that the present deformity is the result of an early operation for the opposite defect. In such cases the advancement of one or both interni, without section of the externi is to be recommended.

3. *Hypertropia*.—The causes of functional hypertropia have been but little discussed. The traditional internal squint of hypermetropia is, according to Stevens (*New York Medical Journal* February 17), to be explained by the associated hypertropia, but he fails to name a cause for the latter. In my opinion hypermetropia is responsible for both, on the assumption that the strain on the accommodation induces overaction of not only the internal rectus but of the superior and inferior recti and of the inferior oblique. The image of the squinting eye is always on a plane lower than that of the fixing eye. Hypertropia in hetero phoria and in low grades of myopia where the accommodation is active, should theoretically be cured by advancement of the superior oblique. This is, however impracticable. In concomitant squint, hypertropia needs no treatment, in constant squint, tenotomy of the superior rectus is often necessary. Hypertropia in myopia (a rare complication) may be traced to a relaxation of all the muscles under the control of the third nerve, when the superior oblique and the external rectus having no opposition the cornea is rotated outward and downward (hypotropia).

4. *Heterophoria*.—The same principles of therapeutics apply to the tendencies to turn as to the actual turnings. A very large proportion of the cases are eso hyperphoria depending upon hypermetropia and astigmatism and require no surgical interference.

5. *Esophoria*.—A course of atropia or other mydriatic paralyzing the accommodation for some days, followed by the wearing of as near as possible, full correction, will often remove the symptoms for which tenotomy seemed to be indicated. Indeed, the presence of esophoria will often indicate latent hypermetropia. Guarded tenotomy of both interni will sometimes cure. It often may be repeated. Advancement is indicated when adduction is weak.

6. *Exophoria*, as exotropia, is a passive condition and can not be directly ascribed to an error of refraction as a constant cause and is due also to an innervational weakness of convergence. Tenotomy is powerless to effect more than a temporary cure. Advancement of the interni will often permanently cure.

7. *Hyperphoria* seldoms demands operation, notwithstanding the extraordinary claims made by enthusiasts. It is to be treated by a correction of the error of refraction which in most cases is its cause. Partial or complete tenotomy is to be performed only when full correction fails. An operation is successful when we can determine binocular fixation for all distances and there is no limitation of adduction or abduction or of lateral movements. Tenotomy as formerly practiced—wide division of the tendon and lateral attachments on the squinting eye only, invariably leads to disfigurement by recession of the caruncle and conjunctiva, and to loss of movement on the side governed by the operated muscle, with homonymous or crossed diplopia or both. Landolt has urged for twenty years that advancement shall substitute tenotomy in all cases of insufficiency and in most cases of strabismus. He reserves tenotomy for these cases only in which advancement has proved inefficient. His reasons are given in his paper read before the Congress in Edinburgh in 1894, to which I refer the reader who is not already familiar with the transactions of the Congress, these reasons are logical and forcible and will no doubt influence those uncertain as to the choice of operation. In my own experience, most satisfactory results have been obtained, in patients in whom I had failed to give more than temporary benefit by tenotomy. My method of operating by advancement is that recommended and, I think, suggested by Savage of Tennessee, with a slight modification. The conjunctiva and capsule of Tenon are dissected away, and the muscle and tendon exposed as far back as may be necessary for the insertion of the sutures. The muscle is elevated on two hooks and freed from its surrounding connective tissue. One needle of a double-armed thread is passed from without inward through the upper, and the second needle through the lower border of the muscle and the thread is drawn tightly, intersecting the muscle vertically its entire width. Each needle is then inserted from above downward and below upward, respectively, through the upper and lower border of the tendon at its insertion—*without separating the tendon from the sclerotic*. Before drawing the threads tight, a small portion of muscle back of the tendon and in front of the suture is excised, in order to oppose fresh surfaces which will more rapidly unite, and to prevent the lump which Savage says is always made. The muscle back of the suture is then

grasped with fixation forceps by an assistant and brought forward to relieve the strain on the suture When the suture is made taut, the knot is tied No conjunctival suture is necessary

TENDON ADVANCEMENT AND TENDON RETROPLACEMENT

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY CHARLES HERMON THOMAS, M D
PHILADELPHIA

Reference is here made to advancement of tendons as distinguished from tendon resection or tendon shortening In the latter two, the stump of the partially severed tendon furnishes the point of attachment of the portion to be brought forward Not so, however, in tendon advancement This operation is required as a remedy for strabismus, insufficiencies, and for the results of old operations excessive in their effects Tendon retroplacement is here recommended as a control procedure, in connection with complete tenotomy, and is to be practiced at the time and as a part of the original operation

It may as well be said at once that in the opinion of the writer, the operation for tendon advancement, as described by Stevens and performed with the singularly delicate instruments which he has given us, may be substituted with advantage for all *other operations heretofore described* The small conjunctival opening with its minimum of integumental traumatism, the almost total-subconjunctival location of the sutures, the unirritating character of the sutures owing to their small size, the ease and exactness with which it may be practiced, and the freedom from after-irritation during the process of healing leave little to be desired

In a single particular only has any modification of Stevens' method seemed advantageous and that relates to the location of the stitch making the attachment to the globe The conjunctival stitch which he recommends having occasionally failed, I have sometimes made a sclerotic attachment not involving the conjunctiva A very small curved needle carrying the 000 000 thread of Stevens' is passed through the center of the extremity of the tendon to be advanced from without inward, and is carried forward to a point within the region denuded by the conjunctival incision and at the point selected for the attachment of the tendon and back of its original insertion The needle is now made to enter and traverse the superficial layers of the sclerotic, tunneling a distance of 1 or 2 millimeters in length and barely deep enough to make a firm hold, the firmness of which hold may be tested after the emergence of the point of the needle by a lifting motion at the hand of the operator The result is the tacking down of the tendon in a perfectly definite way to tissues of sufficient firmness to maintain the fixation of the parts involved until healing shall have taken place

It is to be expected that the result obtained at the time of operation will closely approximate the result finally reached I have frequently found a difference under these circumstances of not more than 1° or 2° The usefulness of such an operation in cases of old post operative deformities is manifest

Tendon retroplacement is in a certain sense a control procedure applicable in tenotomy where accurate dosage is essential In such cases, it not infrequently happens that section of a tendon less than complete severance fails to produce a sufficient result, while a complete section results in an excess For example in a lateral heterophoria of 15° in each eye, not more than 8° or at most 10° can be obtained by partial section—an insufficient correction A complete section may result in 20° to 25° of effect—an over correction Under such conditions, the correction may be made quantitatively exact by first making the complete section and then at once advancing the tendon to the proper point, there tacking it down If we endeavor, as I think most of us do, to make our corrections in equal quantities on both eyes, this procedure will be found not infrequently useful, at times indeed indispensable

It will be seen that this, considered as a control procedure, differs radically from that often employed, in that the large conjunctival wound and the conjunctival suture are here discarded

THE INDICATIONS FOR, AND THE ADVANTAGES AND TECHNIQUE OF, MUSCLE SHORTENING

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY G C SAVAGE, M D
PROFESSOR OF OPHTHALMOLOGY IN MEDICAL DEPARTMENT OF VANDERBILT UNIVERSITY, NASHVILLE, TENN

In the judgment of the author of this paper, muscle shortening is indicated in all cases of heterotropia, regardless of the direction or extent of the turning In many cases of low degrees of squint the shortening operation alone will effect a cure, while, in a greater number of cases, the shortening of the weaker muscle should be associated with a partial division of the tendon of the stronger muscle in order to the attainment of the best results In cases of high degree of exophoria in which a partial tenotomy of both external recti does not reduce the exophoria within the range of possibility of completing the cure by rhythmic exercise of the interni, the latter should be shortened In all cases of exophoria with less than 8° of abduction, shortening of the interni is indicated, not to be associated with even the slightest tenotomy of the externi In high degrees of esophoria not reduced by a partial tenotomy of the interni within the limit of possibility of completing the work by exercising the externi, the latter should be shortened, while in the lower degrees of esophoria, the only operation indicated is the shortening of the externi In any case of hyperphoria not reduced to 2° or less by a partial tenotomy of the superior rectus of the hyperphoric eye, the inferior rectus of that eye should be shortened In all cases where shortening is indicated, except in hypertropia and hyperphoria, the operative effect should be equally divided between the corresponding muscles of the two eyes The superior and inferior recti of a cataphoric eye should be operated on rarely if ever Since the shortening of the recti muscles, associated with partial tenotomies of the opposing muscles can effect so much, a complete tenotomy of an ocular muscle can not be often indicated

THE ADVANTAGES OF SHORTENING a muscle, over the older method of muscle advancement, may be set forth in a few words the former is more easily done, and is the safer of the two operations, in that torsion of the eye is not so likely to occur as a result of setting the tendon too high or too low, in case the externi or interni are the muscles involved, or too far out, or in, when the superior and inferior recti are the muscles in question Should the knot come untied in the shortening operation, the patient's condition will not be worse after the operation than before, which can not always be said when the same thing happens in the attempt to advance a muscle An apparent objection to the shortening operation is the knuckle of the muscle formed by the folding, but this disappears by absorption within a few weeks

THE TECHNIQUE OF MUSCLE SHORTENING

was simple when first introduced, but has grown in simplicity as a result of a modification suggested and practiced by Dr Tenney, of Boston The original operation was performed as follows the eye was cocainized, the lids were separated by a stop speculum, the conjunctiva was seized with fixation forceps a little behind the insertion of the muscle tendon, and two cuts with scissors were made, one vertical the entire width of the tendon and a little behind the insertion, the other below and parallel with the lower border of the tendon and muscle The included portion of the conjunctiva was then dissected up and held out of the way A puncture of the capsule of Tenon was next made, at the lower border of the tendon near its insertion, and another puncture at a corresponding point at upper border of the tendon, through which a strabismus hook was passed beneath the tendon, with which to control the eye A silk thread was then armed with two needles, one of which was passed through the upper part of the muscle and capsule from without in, at a chosen distance behind the insertion, and, similarly, the other needle was passed through the lower part of the muscle and capsule at a point immediately in line with the first Drawing on the two ends, a loop of thread was brought in contact with the capsule over the muscle The passage of these needles was facilitated by lifting the respective borders of the muscle with fixation forceps The next step of the operation was to lift the tendon by means of the hook and pass, first one needle and then the other, through the tendon from within out, at points one-eighth of an inch apart, bringing these needles out through the conjunctiva, a little in advance of the tendon insertion The two needles were now removed and, by means of the surgeon's knot, the part of the muscle beneath the loop of thread was drawn up to the insertion of the tendon, thus shortening the muscle to a corresponding extent The flap of conjunctiva was now allowed to fall down over the knuckle of muscle The stitch thus taken was allowed to remain from four to six days, at the end of which time the muscle was firmly fixed, by adhesive inflammation, in its new relation

The modification suggested by Dr Tenney, in a personal letter, I at once adopted As thus modified the operation is done as follows a horizontal cut is made with scissors through the conjunctiva and capsule of Tenon, beneath the lower border of the muscle from the insertion of the tendon backward, to the extent of the shortening desired Through this cut two strabismus hooks are passed,—one beneath the tendon at its insertion, the other beneath the muscle By means of these hooks the muscle is lifted from the sclera A needle is now passed through the conjunctiva and the upper border of the tendon at its insertion and is carried back beneath the muscle to a point chosen just in advance of the second hook, where it is made to penetrate the muscle near its upper border and the superposed capsule and conjunctiva The needle is then made to reenter the puncture in the conjunctiva made by it in its exit, is directed downward between the conjunctiva and the capsule and is brought out through the incision in the conjunctiva Then the lower border of the muscle and capsule are seized with forceps and this needle is made to penetrate them from without in, and is again brought out through the horizontal incision The needle is now passed through the incision beneath the tendon which it is made to penetrate at the lower border of its insertion and is brought out through the conjunctiva at a point in line with, and one-eighth of an inch below, the primary puncture The two ends of the suture thus passed are now brought together by a surgeon's knot with enough force to bring the part of the muscle beneath the loop in contact with the tendon The suture is allowed to remain from four to six days

The suture plate, recently introduced by Dr Chalmer Prentice, of Chicago, as modified and improved by Dr George H Price, will most likely be of much service in this operation, if for no other reason than that it will greatly facilitate the removal of the suture The *improved plate is made of aluminum, is five sixteenths of an inch long and one eighth of an inch wide, oval in shape* In this plate there are two holes one-eighth of an inch apart, through which the two ends of the suture are passed In tying the suture, the plate, which has such a concavity as to fit the curvature of the eye, is brought in contact with the eye, and the knot is tied over it between the two holes There is a transverse groove near one hole along which one blade of the scissors is passed when the suture is to be removed

SLIGHT EFFECTS OF TENOTOMIES OF THE OCULAR MUSCLES, AND WHAT ARE THE INDICATIONS AND ADVANTAGES OF TENDON CONTRACTIONS?

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY GEORGE T STEVENS, M D
NEW YORK

1 *Technique of Tenotomies*—I have placed my views so clearly on record respecting the general technique of tenotomies that it does not seem necessary to repeat what I have said There remain for discussion these two questions

1 Why are slight effects produced as the result of free tenotomies of the ocular muscles?

2 What are the indications and advantages for muscle shortening?

In regard to the first question, the slight effects sometimes resulting from free tenotomies, I shall venture the assertion that a tenotomy uniformly produces all the effect which we have a right to expect from it If we hope to produce a definite effect, by operating on a muscle which is not the chief element in the condition for which we operate, we may expect disappointment In other words, we shall not get the effect for which we hope, if we operate on the wrong muscle

It is necessary always to take into consideration all the reasons all the conditions which enter into the anomaly for which the operation is to be done All cases of esophoria, for example, do not of necessity depend upon any anomalous relations of the external and internal recti muscles We may have, and indeed we do have, many cases of deviation or of deviating tendency of the visual lines inward which depend, not upon a false relation of the lateral muscles but upon too great tension of the vertically acting muscle As to exophoria, I suspect that, as an essential and original condition, it is of much less frequent occurrence than is generally supposed Indeed to an important but not to the full extent, I may express my present view on this subject by repeating what I said in a paper on exophoria in 1889 (*Archives of Ophthalmology*, xviii, pp 4, 373), and in which I called attention to the fact that free tenotomies of the externi often produce less pronounced effects than might be supposed I there gave as a reason, "that exophoria is not infrequently the expression of hyperphoria is a fact that can not escape the notice of the careful observer"

In the same paper, a thought which had more strongly impressed itself upon my mind than I was then ready to fully express, was stated as follows

"When the relative physiologic power of the externi and interni are considered, we may well question whether exophor a is often a congenital defect" I did not then think that the available facts warranted any assertion, nor am I at present ready absolutely to exclude exophoria from congenital anomalies, but I feel warranted in saying that it is in every case safe to assume that it is an acquired condition, although careful consideration may at length lead us to adopt the view that a given case is an original and essential anomaly

I have shown in papers which have been published from time to time during several years, how converging strabismus may often be relieved by proper relaxations of the overacting superior or inferior recti, and one who gives the subject careful study will be surprised to find how large a number of squinting people, squint in or out, not because of an excessive or of an insufficient normal tension of the lateral muscles

I present here the photographs of two patients, each with marked converging strabismus, also a photograph of each of these patients in which it is plain to see that, whatever other anomalous condition may exist, or whether the best or the worst way has been adopted, neither of which questions is raised in this connection, a notable change has occurred in regard to the converging squint In fact, it has been abolished, and yet in neither of these cases has there been the slightest interference with the lateral muscles, but in each case there has been a relaxation of both superior recti

Now, let us suppose that in either of these cases a tenotomy of the internus had been done (as had been strongly urged by distinguished surgeons in both cases), is it not plain that a positive injury would have been done? But is it not also plain, and this is the bearing of these cases upon this question of free tenotomies and small results, that if these eyes were caused to swing in, by virtue of the action of the vertically acting muscles no tenotomy of an internus, short of turning the balance of the eyes distinctly outward, would have served to prevent the inward squint? After such a so called "correction," comes, very naturally, the gradual divergence so often seen after squint operations

But there is in all this an element of great importance which has been generally overlooked, although I have called attention to it more than once This free tenotomy which has caused so little apparent change in the appearance of the eyes when directed straight forward, has caused a marked, and generally an unfortunate disability of the eye to rotate in the direction of the free tenotomy

Time, in this discussion, will not permit me to go into detail in regard to these conditions, but I may in a few words call your attention to some important truths

An unfavorable direction of the eyes with regard to the horizontal plane, in which by virtue of a preponderating action of the upward or downward drawing muscles of one or both eyes, equally or unequally, an excessive effort is demanded on the part of the opposing muscles, predisposes to a drifting in or out of the visual lines according to circumstances If the disproportionate tension of the vertically acting muscles is exactly equal, esophoria or esotropia usually results If there is excessive and unequal vertical tension, exophoria or exotropia often results

This being the case, it becomes a matter of the first importance that we determine not only the absolute but *comparative rotations of the eyes, not only* from side to side, but up and down

We have had until quite recently no sufficient means for determining these rotations The judgment which we may form by watching the rotations is not to be relied upon The perimeter is destitute of any considerable value for this purpose

The instrument which I show you here and which I call a tropometre, serves in this respect a valuable purpose It consists essentially of a telescope in which the inverted image of the examined eye is found at the eye piece, where either as an aerial image, or as an image upon a ground glass, its movements can be accurately observed A graduated scale in the eye piece permits every movement of rotation in every direction to be exactly measured For the purpose of convenience in being near the patient and of presenting no obstruction to the light which should fall upon the examined eye, a right-angled prism or an obliquely placed mirror is adjusted at the distant end of the telescope, permitting the examination from the side instead of from the front

Now, if we study the vertical actions of the eye muscles in connection with the lateral we shall find that we have rarely, indeed, I think I shall not be betrayed into an exaggeration if I say that we have *never* to make very free tenotomies in any direction, for even in cases of extreme squint inward or outward, when we have accomplished the *first stage of* correction, which should be that of establishing equal and proper rotations up and down, there will remain *so little to do that a complete* tenotomy of an internal or external rectus muscle can never be required In short, if we attend to *all* the elements which enter into the production of a lateral squint, instead of directing our attention exclusively to one muscle, and that generally the wrong one, we shall never have occasion for great operations

Now let us turn our attention to the question of indications and advantages of tendon advancement

The question turns first upon the purpose for which the operation is to be done If it is for the purpose only of "straightening a cross eye," which is the purpose so often, then I have no interest in its discussion It makes little difference how it is done It is a subject belonging neither to science nor to high art

But if it is done with the definite and intelligent purpose of establishing binocular vision *at all normal points and under all normal circumstances*, we have a question of the highest scientific value and calling into service some most delicate and beautiful principles

Many years ago I advised, when there appeared a necessity of making a very free tenotomy, to divide the effect between a moderate contraction of one muscle and a moderate tenotomy of its opponent, doing each upon both eyes, thus leaving the tension of the two opposing muscles as nearly as possible equal in sum to the original tension but with the amount so divided as to bring about the desired effect Superficially this appeared to be good logic and sound practice As a matter of fact, it was neither the one nor the other

We must recur to the principles which I have already discussed in regard to tenotomies We must first ascertain exactly why an eye deviates in this or that direction, and then, if surgical operations are required, we should inquire whether the tensions are too great or too small And, exactly here, upon the answer to this question, should the selection of a method be determined How are we to know? Does the fact that, for example, in converging strabismus the eye rotates too far in and not far enough out, tell us what to do?

I know of but one method of solving the question absolutely We may do this by the tropometre

Let us, for illustration, assume that the temporal rotation should normally be 45° and the nasal 50° of an arc This would give us the sum of a normal rotation in the lateral directions of 95° Then, suppose that the upward rotation should be 40°, and the downward rotation 48°, the sum would be 88° Now, should we find in a given case that the sum of these rotations should largely exceed the amounts given, it would be an indication for tendon shortening I have found the percentage of these cases very small The eyes of such people are usually, if not always, very prominent—almost goggled The movements can be seen to expose large tracts of conjunctiva and the eyes swing in or out, according to the conditions of fixation

By far the greatest number of those who have lateral deviations show no such excess of rotations They are in the great majority restricted to three fourths or even two-thirds of the normal rotations To tie up such muscles and to increase the already excessive tension may be to improve the appearance of a patient, it certainly adds nothing in a rational way to an actual correction of the disabilities of rotation I do not question the claim that eyes may be brought into closer relations in certain directions by such forcing, but I greatly question the wisdom of the method

We may then sum up an answer to the questions which have been presented in a few words

Free tenotomies have slight apparent effect when the muscle operated on is not the muscle at fault, and tendon contractions are advantageous only when they are directed against a condition of muscles positively shown to be loose, not by the failure of the eye to rotate in a single direction, but by a marked excess in the sum of rotations in opposite directions

To draw a useful lesson from these few suggestions, I would say that a case of strabismus convergens or divergens is to be studied from the standpoint of the tensions of all the eye muscles, and that a very large proportion of these, and especially those of high degree, are the manifestations principally of vertical tensions

If the rotation upward of the eyes, as shown by the tropometre is materially less than 40° or 45°, while the downward rotation materially exceeds 50° or 55°, no correction for the lateral deviation should be made until the rotation upward equals 40° and hyperphoria is absent Or, if the upward rotation is excessive in comparison to the downward, an analogous correction is first to be made before an internal or an external rectus is cut

If the rotations in all directions are evidently too great, indicating an absence of proper muscular tension, tendon shortening may be resorted to, which will be very rarely If the sum of the rotations is not excessive, tenotomies only are called for

TO WHAT EXTENT SHOULD RECENTLY SUGGESTED SYSTEMS OF MUSCULAR EXERCISE DISPLACE TENOTOMY IN THE TREATMENT OF HETEROPHORIA?

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md , May 7-10 1895

BY HIRAM WOODS, M D
BALTIMORE

One's conception of the physiologic importance of an abnormality necessarily enters into his estimation of therapeutic measures The wide difference of opinion upon the importance of heterophoria makes it advisable to state one's position before reviewing therapeusis Briefly, I think heterophoria, like refraction errors, often is comfortably borne Further, I am in accord with Dr Duane[1] that we must find what heterophoria means "Whether it is a spasm or paresis, accommodative strain or anatomic conditions that are the cause of the heterophoria" In some one of his papers Dr Stevens has said that the surgical correction of a functional abnormality is a matter of grave responsibility In a word, the whole matter is a question of diagnosis, and a mistake may be very serious Exophoria is not always weakness of the interni The same is true of faulty tendencies in other muscles Free tenotomies sometimes produce slight effects, and careful tenotomies sometimes produce disastrous and great effects The surgeon who escapes such an experience is to be envied In 1893, Dr Savage[2] gave out his "Rhythmical Exercise" At the Pan-American Congress in September of the same year, Dr Gould told us we had "all been on a surgical debauche," and followed his indictment with his treatment based upon the theory of "Innervational Abnormalism"[3] It was interesting to note the avidity with which these measures were seized upon where these distinguished writers have established influence From the South and West came cures by rhythmic exercise when everything else had failed

[2] Ophth Record, May, 1893
[3] Medical News, Nov 18, 1893, and Annals Ophth and Otol Jan 1894

Around this neighborhood, "handicapping by prisms" reigned supreme The meaning of it all was that there is a widespread conviction that tenotomy is not always a safe remedy for heterophoria, nor the balance test the whole diagnosis Personally, both measures appealed to me as rational I have never felt that it was in accord with scientific work to restore muscular balance by weakening the stronger muscle To bring the weak to the physiologic standard of the strong seemed the correct procedure This is what these plans proposed to do Again, I had met cases where, with faulty tendency by equilibrium test, there was wanting what Dr de Schweinitz[4] gives as a necessity for tenotomy, "distinct preponderance of the opposing muscle" In looking for this preponderance, with esophoric balance, the variableness of adduction had led me to abandon it as a test I was satisfied that adduction was nothing more than positive relative range of convergence, and largely a matter of cultivation, moreover that it bore no constant relation to balance, for with high exophoria it was often high also This bit of observation, with the influence of certain writers, had led me into an error, which, I believe, is common I mean the extension to abduction of the same reasoning applied to adduction The latter is variable, can be easily increased in a variety of ways, and bears no constant relation to the distance equilibrium test It has a connection with accommodation of uncertain and variable nature None of these, it seems to me, are true of abduction It varies, if at all, within very narrow limits, it is rarely, and with difficulty, increased by any system of exercise with which I am familiar, it has no necessary physiologic nerve connection with another function, from which the patient must learn to divorce it, in a word, it forms, with distance equilibrium test, and associated refraction, the keystone of diagnosis It is, I believe, always low when esophoria means intrinsic weakness of the externi, always high when exophoria demands surgical treatment In either esophoria or exophoria, without low or high abduction, there is something else, and a tenotomy before this something is discovered is a hazardous undertaking

Answer to the title question must come through answer to another What does clinical experience teach can be accomplished by the two methods of exercise mentioned? and, farther, it is to be remembered that faulty lateral balance does not always mean intrinsic muscular weakness At the hands of Drs Duane[1] and Eaton,[5] Dr Gould's plan has undergone investigation from the standpoints of originality, physiologic correctness of nomenclature and usefulness Each of these writers thinks that the method is an adduction developer, a promoter of positive relative convergence Of this there can not be the slightest doubt Adduction can be doubled or tripled often in five minutes So far, then, as defective adduction causes exophoria, it is a remedy for exophoria In its clinical use I note 1, adduction when low can be developed most rapidly when associated with low or normal abduction (3° to 8°) This condition is not true interni weakness, although the balance test is usually exophoric It is only inability, from causes little understood, to separate convergence from accommodation 2, defective relative range of convergence may cause asthenopia By way of illustration

Case 1—Student 21 years old Asthenopia on near work Refractive condition Hm+1 D, Ht under homatropin, +1 5 Muscles, at 20′, exophoria 1°, Ab 3° Ad 10° Near exophoria 10° with naked eye 14° with *Hm corrected* Gould's method raised adduction to 24° in five minutes Allowing a normal excess of exophoria for the near over the distance balance of 2°, there was left a near exophoria of 11 prism degrees, or 3 meter angles This was 1 5 m a for each eye In other words, the muscular error for the near, corresponded exactly to the accommodation in dioptres for distant vision Hm (1 D) was ordered for constant use, and Gould's method continued for a few days Adduction was easily developed to 30° and stayed there Behind the glasses near exophoria fell in three weeks to 8°

I noted this same condition in another case a medical student 23 years old He had Hm+0 5 D, Ht +1 25 Muscles, at 20′, exophoria 1°, Ab 4°, Ad 14° Near exophoria 11° Prolonged work was an impossibility The calculation for meter angles shows nearly the same relation to H as in Case 1 Gould's method made adduction 30° in a few minutes It was continued for a few days, and the *Hm* was corrected Behind these glasses, near exophoria fell to normal in three weeks

Three possible causes of the asthenopia suggest themselves 1, hyperopia Uncomplicated hyperopia of 1 5 D total in healthy young men, with p p acc of 6 or 6 5 cm is not apt to produce asthenopia 2, the low abduction Convex spherical glasses are often of great service in weakness of the externi In such cases, however, there is usually low exophoric balance at 20′, with either the same or orthophoria in the near High near exophoria is not a symptom of this condition 3, defective relative convergence The usual near balance is 2° to 5° in the direction of exophoria, compared to distance balance Dr Noyes[6] thinks this is not abnormal Dr Theobald[7] had developed from it a useful method of diagnosing accommodative asthenopia in young persons In each of the above cases the excess of near exophoria, over this normal, equalled the difference between A and C imposed by refraction error Under exercise which broke up the hard and fast artificial connection between A and C, symptoms disappeared, and near exophoria gradually lessened behind *convex* glasses, just the opposite of what is usual The conclusion seems justifiable that defective positive relative convergence was the cause of asthenopia I have treated similar cases with abducting prisms for near work Such a course is often successful, but it only treats a symptom Gould's method breaks up the cause of asthenopia, and refraction correction prevents its return

A third note I make for the clinical use of Gould's method is that in exophoria, with high abduction, development of adduction, without attacking the overstrong externi, sometimes relieves In the case of a man 21 years of age, without refraction error, and with asthenopia, I found exophoria at 20′ of 1° to 3°, Ab 10°, Ad 12° Near exophoria 9° It took several days to develop adduction to 30°, but then a cure was effected Exercise was continued for several weeks Apparently this was a case where the intrinsic muscular error, overstrong externi—was easily carried as soon as the interni were taught to work In favor of this method, the above is all I can say In esophoria it has failed me utterly Abduction has not increased In one case of hyperphoria it seemed to do good, but it is distinctly inferior to Savage's rhythmic exercise In exophoria with high abduction, it has only exceptionally relieved asthenopia, though it developed adduction from 10° or 15° to 50° or 60° The trouble was excessive external contraction In several such cases I have had to order abducting prisms or do external tenotomy Still, the method was useful as a diagnostic means, to throw the responsibility on the strong externus, and acquit deficient adduction Some one I think advocated its use after external tenotomy This seems rational

[4] Diseases of the Eye, p 544

[5] JOURNAL AMERICAN MEDICAL ASSOCIATION, Sept 1, 1894

[6] Diseases of the Eye Edition 1890 p 195

[7] Transactions Am Ophth Soc 1891

Savage's rhythmic exercise has not received, in this part of the country, the attention it merits It is, as Eaton[5] has said, a physiologic method of strengthening muscles I have had considerable experience with it, using for esophoria prisms from 3° to 5°, and for hyperphoria from 1° to 2 5° These are a little stronger than originally advised by Savage I value it highly in these classes of cases 1, in hyperphoria, usually of low degree, where supra- and infra-duction are not far apart, for instance 2° to 2¼°, 1° and 1 5°, etc This form of muscular error, is I believe, quite a common source of asthenopia For my own part, I want a bigger margin than 3-4° when cutting a vertical muscle 2, in low esophoria, with abduction of 2 5° to 4°, unrelieved by refraction correction, it has in a few cases developed abduction a little It is, however, confessedly slow and such cases do better, it seems to me, with adducting prisms 3, when opposite muscles are deficient in contractile power, irrespective of balance test, for instance, a condition like this, esophoria 2° with Ab 4°, Ad 12°, developing hardly at all by Gould's method, and no light thrown on the matter by near test Such cases are not frequent but they occur, and are due to general muscular asthenia

Rhythmic exercise seems to me the only rational treatment we have In the case from which the above measurements were taken, it gave excellent results As a developer of adduction it is slower than Gould's method

To answer the title question, I would conclude that 1, Savage's rhythmic exercise should displace tenotomy in the treatment of low hyperphoria, when supra- and infra duction are not over 1° to 1 5° apart, 2, when, irrespective of balance, all the muscles are wanting in contractile power, 3, when a weak externus, with only 3° or 4° abduction, (5° being regarded as the normal minimum) seems to cause trouble, and there are wanting the conditions which make internal tenotomy justifiable

I would conclude that Gould's method will 1, almost certainly give relief in the considerable class of cases where exophoria and low adduction exist without high abduction, 2, that even when exophoria is associated with high abduction, adduction should be developed by Gould's method before operating, to determine whether it is excessive externus or defective internus action that is causing asthenopia

In esophoria with low abduction, or hyperphoria with a difference in vertical duction of 3° or more, refraction correction or prisms, bases toward the weak muscles, having failed to relieve, operation is as a rule necessary The ideal treatment for heterophoria, due to intrinsic muscular weakness, is a system of exercise which can be depended upon to develop very weak muscles to the strength of their antagonists It has not yet been discovered, so far as I know

ELECTRO-VIBRATION OF THE TURBINATED TISSUE

Read in the Section on Laryngology and Otology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md May 7 10, 1895

BY J MOUNT BLEYER, M D, F R A M S

Member of the Royal Academy of Medicine of Naples, Italy Corresponding Member to the Academy of Medicine of Mexico, Corresponding Member De La Société D' Electrotherapie, France Member American Medical Association Surgeon to the New York Throat and Nose Hospital Surgeon to the German West Side Clinic Medical Editor Electrical Review Electrical Society, New York City, etc

NEW YORK

In this paper I shall attempt to present the useful purpose of faradism, as observed by me, in treating this form of disease involving certain conditions of the turbinated tissues, which from time to time we have been treating according to the prevailing fashion of the moment, now medically, then again by the more radical means of surgery, the cautery, the saw, the snare, involving a tissue destruction to which, in some instances I have been for a long time opposed, and which I also availed myself of in the hope that some day I would hit upon a better plan of procedure, more physiological and less often accompanied with results ranging from beneficial to positively bad, if not, to say the least, lastingly harmful

I believe, from the results of two hundred cases treated by the method as I shall describe without going into the details of each individual case, I have found a method for the treatment of simple hypertrophied turbinated tissue that is far better than either the medication treatment or surgery, or both combined It is faradic massage

The time has come when those of us who have given years to the careful study of the curative power of electricity must plead for tolerance among our colleagues, and an impartial hearing Electricity has many uses, and I am sorry to say many abuses, which in no few instances come from so called specialists, ranking high as leaders in the slowly growing science of electro-therapeutics

Electricity is like copaiba in emphysema, a good remedy in bad company

The good account faradism has rendered of itself in this instance is due to the fact that we have studied and carefully observed its physiologic action and have just begun to bring it under the control to which all remedies are subject, that of intelligent dosage This has been rendered possible by the recent improvement in faradic machinery

By means of induced currents (faradic electricity or interrupted current) very powerful currents can be obtained, but currents which only last a short period of time If we wish to apply the induced currents therapeutically or for experimental purposes, we must find means of generating them in quick succession An apparatus for this use is called induction apparatus or a faradic battery To be more explicit the essential parts of an induction current machine are spirals with iron cores, which are moved quickly past magnetic poles An ordinary faradic apparatus would then consist of a primary coil, having an iron core, and a secondary coil which is wound over the primary coil Through the primary coil a galvanic current is passed, the make and break of which follow rapidly upon each other In order to produce this phenomena which is necessary for the rapid interruptions of the current in the primary coil, an automatic circuit break is provided This may be simply a vibrating armature of an electro magnet, alternately energized and de-energized, which armature in vibrating alternately makes and breaks the primary circuit Such arrangements are usually in small induction coils

The three illustrations below inserted explain the principal points regarding the construction and physics of an induction machine (Fig 1)

1 Illustrates a galvanic current which sweeps around the primary coil C ′ while (*a*) converts the core into a magnet, N S and (*b*) induces a momentary reverse current in the secondary coil C ′′

2 The sudden magnetizing of the coil itself induces a reverse current in the secondary coil, which strengthens the galvanic induced current within this circuit

3 The magnetized coil attracts the soft iron head of the spring to itself, and so breaks the current flow

4 This stopping of the current flow stops the magnetizing influence upon the core, and a direct current is induced in the secondary coil by the breaking of the primary current, strengthened by that induced by the de magnetization of the core

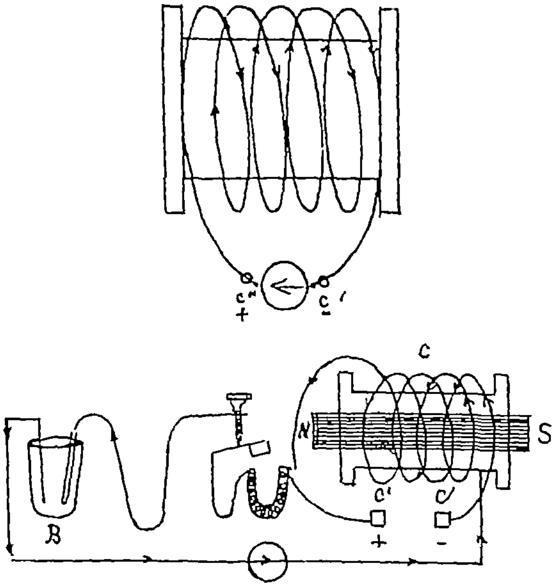

Fig 1 —Faradic Apparatus, showing its Outlines and Principle of Construction

5 The magnetic force holding the hammer being removed, it returns by another current, passes, and by these vibrations the process is repeated in such rapidity as the strength of spring and magnet admits

Definition of Induction —What is induction? What are induction coils? By common consent this term is employed as a name for an apparatus invented by Munson and Neef and subsequently by M Ruhmkoff, consisting of a bobbin wound with a short coil of stout wire, over which is wound a secondary coil of very fine wire of many thousand turns, well insulated from each other, the whole fitted with a central core of iron The name is not happily chosen It should have been inductive coils, since the word “ inductive” means “ leading, persuasive, producing,” and the use of these coils is to produce a high tension electric current from one having a low tension The term inducing coils, would have been still more correct since inducing is part of the verb induce, a word meaning, “ to influence, to persuade, to actuate, to impel, to allure ” The appropriateness of these terms to the electrical instrument under consideration will be seen as we proceed in explaining the principle of their construction, and their mode of action The word “ induction” on the other hand, comes from the verb “ induct” which means “ to introduce, to bring in, to put in possession,” none of which apply appropriately to the action of the inducing or inductive coil Now scientists have given different definitions for the term “ induction,” but most of them are not clearly defined Perhaps it will be more easily understood if put in the following words

THEORY OF INDUCTION

Every theory respecting induction is based on the assumption that there existed two electricities, one positive and the other negative, both of which were fluids The fluid theory has been abandoned by electricians, because modern observations of electrical effects have rendered the theory no longer tenable The other theories of two electricities, that is, two kinds of the same thing, such as positive and negative, answering to the terms male and female, is also fast passing away We still speak and write of electricity as being positive and negative, but we use these terms most to distinguish the backward or forward movement of the current, than to employ the existence of two separate and different forms of energy Some of the newest theories respecting induced currents of electricity are based on the assumption that all bodies are enveloped in a fluid, to which the name of ether has been given The electric current, in passing through a conductor, disturbs the arrangement of its component parts and these in turn are said to disturb the ether, which then transmits the disturbance to contiguous bodies Whether this theory is based on fact or on fancy we can not here determine, but the fact remains that there is such a disturbance set up in bodies near to electric conductors, and these are especially observable at the instant when the current of electricity is interrupted, as when the electric circuit is broken The observed effects go to show that the interruption causes a kind of eddy or back-wash in the current, which is felt by other bodies susceptible to its influence and observed in them as a current flowing in an opposite direction to that of the inducing current The inducing effects are more strongly shown in conductors actually in contact with the insulating substance, but they are also observed in conductors separated by air spaces only from the inducing conductors This goes to show that either the air or some similar invisible conducting medium transmits the inducing effects of one conductor to another conductor

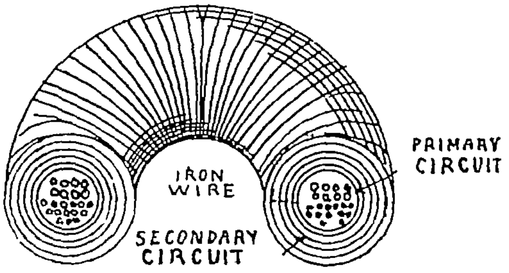

Fig 2 —Section of ring shaped Secondary Generator or Coil

PRINCIPLES OF INDUCTION

Before we proceed further in the study of the induction or inductivity, it will be advisable to notice a few of the principal facts or laws governing its action These, when well understood, will guide us regarding the construction of coils and the faradic machine, or induced current apparatus

The inducing conductor and the conductor to be induced must run parallel, side by side The inductive effect is weakened when they cross each other, and may be neutralized by a transverse position The bare conductors must not touch each other, but must be separated by an insulating medium If two conductors are in contact at any part of the circuit, or are insufficiently insulated, they combine in forming one conductor conveying the primary current in one direction only, and consequently there will be little or no inductive effect observed The turns of the conducting wires of a coil should not only be wound regularly, side by side, to get the best effects, but should also lie close to each other, separated only by the thin insulating medium

Since each turn exerts an inductive influence on its neighbor, and this influence is weakened by over-insulation and want of continuity, it will be seen further on, when we consider the relative values of insulating mediums, that the best of these are conductors of electricity, when the tension or pressure of the current is sufficiently high to overcome their resistance Therefore in planning the insulation of the wires and the parts of a coil, regard must be had to the tension of the current employed in working it, for if we employ a current of higher tension on an imperfectly insulated or badly arranged coil, with a view to obtaining better effects from it, the extra current forced through the coil will overcome the resistance of the insulation and break it down

Whenever this occurs in a coil, the inductive effects cease because all the imperfectly insulated turns are absorbed

The inductive effects of a current are observed, at least these manifestations

1 When the insulated conductor is wound as a wire around a mass of soft non-magnetic iron, the current of electricity passing through this conductor induces magnetism in the iron and converts it into a magnet while the current is passing The effect here manifested as magnetism only exists while the current is passing through the conductor, and when the current is broken

2 When the insulated conductor is doubled on itself, or wound into a spiral or made into a coil with or without a core of soft iron, the inductive effect of one turn of wire on another is manifested at the terminal of the battery or other generator of electricity (when the circuit is broken) by a bright spark, which increases the brightness with the turns made by the wire A similar spark is observable at the terminals of a wire around or laid parallel to the conductor in the main circuit, when the necessary conditions are present This effect is only observed at the instant of breaking contact with the battery, or, in other words, on the instant of the rupture of the main circuit wire

3 When a wire is thus made into a long spiral with several coils close-to each other, and the bared metal parts near the battery terminal are held in the naked and moist hands of a person, that person will experience a tingling sensation in the nerves of the fingers at the instant when the current is broken and also when contact is made again with the battery This manifestation of induction is also only momentary, but can be repeated as often as contact is made or broken When a long coil of fine wire is wound on and over the main coil, the tingling sensation can be felt at the terminal of the second coil when contact is made or broken at the terminal of the first coil

There are, therefore, three distinct manifestations of electric current induction, or the inductive effect of the electric current observable, viz , the magnetic, the calorific and the physiologic All these three effects can be found, described, and its experiments shown in detail in all works on physics

SOME OF THE PHYSIOLOGIC ACTIONS OF INDUCED CURRENTS

The duration of induced currents has marked influence upon their physiologic effects The constant current of a battery only affects our system when a great many elements are used, and the weaker constant currents only affect very sensitive parts, our nervous system, however, is very sensitive to rapid electric changes The induction current, therefore, produces far more powerful shocks than the primary current, because the duration of the former is far shorter than the duration of the latter The difference of duration in induced currents when massive cores or bundles of wire are introduced in the coil, explains the marked difference in their physiologic effect By introducing solid matter, the duration of the induced current is increased, by introducing a bundle consisting of many fine wires, the duration of the induced current is lessened, therefore the physiologic effect is far more powerful, this has been proved to us by Magnus beyond a doubt, and bears important relation to the action of such an induced current in its physiologic action The effects which are produced in general in any given cases under treatment by electricity are stimulating and tonic effects, general and local, these belong to both galvanism and faradism, but especially to the latter, which acts as a stimulus, partly upon the contractile tissues, both directly and through their motor nerves, partly by its sensory nerves and partly in a reflex manner through the vasomotor system, producing increased vascular activity in the parts which it reaches These effects are, to a certain extent, shared by other modes of stimulation, as for instance, by massage, by treatment with hot and cold douches followed by friction with a rough towel, etc , but electricity has certain advantages over these active modes of stimulation, especially in all paralytic affections, from its greater power of inducing muscular tissue construction, and by its vibratory and stimulating action upon the nerve filaments for quite a distance of their length, and from the ease with which it can be directed to any required parts or centers in the body

The effect which peripheral stimulation exerts upon the central organs plays an important part in electrical treatment and affords the best explanation of the benefits which follow, even in cases where the treatment has been applied to the peripheral parts only

THE DIRECT EFFECT UPON THE SENTIENT NERVES BY THE INDUCED CURRENT

The healthy sentient nerves, which are the nerves of sensation, are observed by the aid of the microscope to be arranged in their peripheric termination much like fine moss, or the pile of fine uncut silk velvet If this vibratory action of the induced currents is brought to bear upon the nerves in the nose, the sensation received by the membrane during the passage of the current is as if painfully scratched

The induced current in a given bearable quantity and intensity has a greater effect upon the sentient nerves, in proportion to the frequency of the interruption of the current, *up to a certain degree*—which, for instance, may be about all the nerves can bear, but if the vibrator on any machine is screwed up a trifle, so as to make the interruptions extremely fine and rapid, then the current is more easily borne, and not only so, but it then becomes almost or quite pleasant But I am of the belief there is in this case more indirect effect, i e, reflex action, because this current more nearly resembles the continuous galvanic current A pretty rapidly interrupted current has more effect on the sentient nerves than very slowly interrupted currents, because it is the law of their action to feel or retain the effects of an impression for some little time after being acted upon So where a sentient nerve that is in health is subjected to the action of a single blow of an induction current, if of low tension, there is almost no sensation, but if these blows or shocks are then repeated faster and faster, the sensation will likewise increase, because the sentient nerve is not now in its normal state, i e, when it receives the second and third and succeeding shocks, but is in an excited condition

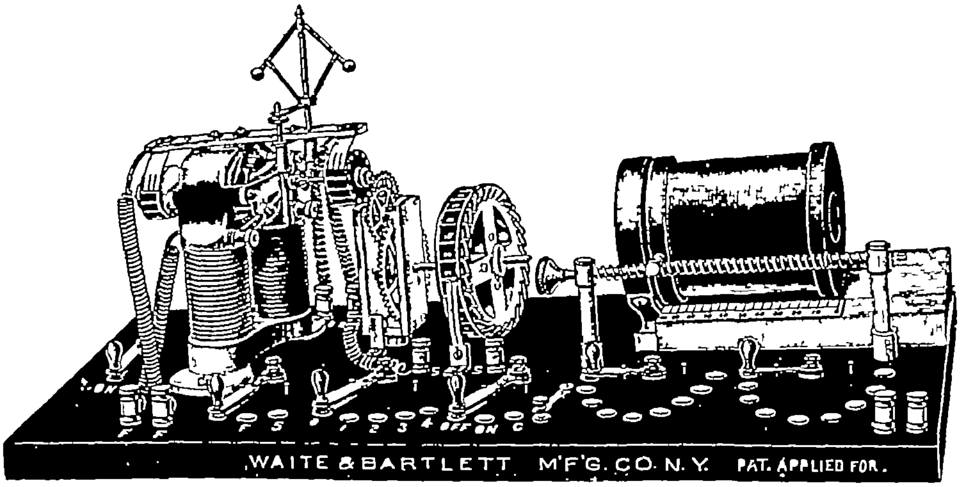

Fig 3—Engelmann's New Faradic Machine, with Variable and Controllable Interrupter and Alternator, of High Tension

There is no doubt that the rate of vibration is one of the most important factors in determining the therapeutic effect of the induction current, and not merely as it was formerly treated, a mechanical necessity for the production of such currents, and a very secondary part in the apparatus, as it has always been and still is in all faradic instruments However, regularity of vibration or interruption is essential to a serviceable therapeutic current and to obtain this we must not only have an interrupted action with far greater regularity than the old-time vibrator as ordinarily constructed, but, in addition, the vibrator must be controlled by a separate force entirely distinct from the coil current, as it is in the apparatus

The remarkable results of vibratory action have been sufficiently demonstrated of late, and the varying effects of such vibration of various mediums upon different nerves are] the subject of physiologic and therapeutic experiment. The more varying the effect of different rates of vibration, the more important is their perfect control The increased rapidity of interruption and the ability to control it gives a wide scope to the efficiency of the current, increases its sedative power, and renders the application of effective currents possible to the most sensitive tissues, certain results, especially decided vasomotor effects, being produced by rapid interrupted currents which are no longer perceptible to the sensory nerves

Dr Engelmann and myself have placed two new appliances constructed on similar principles, mine having some other advantages which will hereafter receive extra description, capable of giving us high rates of interruption, together with a perfect control of those interruptions Vibrations from 1 to 100,000 per minute are obtainable I am also of the same belief with Dr Engelmann that 50,000 interruptions to the minute is ample for all therapeutic uses in connection with the primary and secondary coils as now used in practice By the use of these mechanical devices, the rapid interruptions which they give are a most valuable means placed in our hands We can employ strong efficient current without discomfort

Electro-vibratory massage is the art of applying an intermittent, induced or interrupted current—(faradic electricity) with a specified amount of makes and breaks—periods or interruptions by means of an electrode directly to the hypertrophic turbinated tissue within the nasal cavity, or other parts to be treated by this method As a contrast to electro-vibratory massage usually spoken of, is the act of applying intermittent pressure and strain to the muscles and other accessible tissues The means employed are rubbing, kneading and light pounding, combined ordinarily with more or less additional stimulation of the skin—as by the friction and slapping This manipulation furthers the removal of lymph from the parts, which is especially needful when the lymphatics flow is sluggish through lack of muscular exercise, it apparently quickens the blood circulation through the part and furnishes gentle vasomotor exercise, it acts possibly as a direct trophic stimulus to muscular and sustentacular tissues, by stretching the ligamentous structures it maintains or increases suppleness, in the abdomen it stimulates and aids peristalsis and as a general stimulation of sensory nerves it may affect favorably the nutrition of the central nervous system

In the foregoing part of this paper, under the heading of the physiologic actions of the induced current, I have rehearsed in detail the effects and therapeutic value

It has demonstrated itself to me in all cases that electro-vibration acts directly on the part undergoing the vibration It influences the circulation in the veins and lymphatics, and at the same time acts as an anesthetic where congestions are present, as in acute and chronic inflammations, which will at once make itself evident to the operator The gross physiologic action by applying these high rate vibrations to the turbinated tissues is simply hastening the absorption of the inflammatory processes, and thereby reducing the size of these bodies which occlude the meatuses

By this system which I have been practicing for ten months and applied in over two hundred cases, I can only say that results are most satisfactory to myself and to my patients A very important effect is noticed by the patient immediately after the first séance, that the turbinated bodies have been reduced and breathing is possible through the meatus which previous to the application was occluded The secretions are more abundant and the entire head has a feeling of clearness, which is due to the reduction of the tissue, emptying of blood vessels and lymphatics, and the effects of an impression left by the high speed interrupted current on the sentient nerves for some little but appreciable time after being acted upon Different sensations are felt by different individuals—as pinching, prickling and, most often experienced, a burning sensation as above described These are most of the physiologic and clinical facts connected with electro-vibration, which I tried to describe as graphically as possible

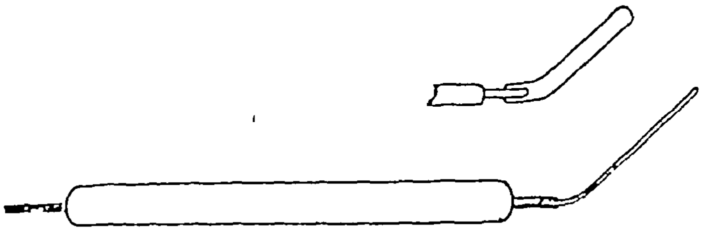

Fig 4 —Author's Electrodes for Electro-Vibration

Cases must be selected for the treatment by this method

THE PRACTICAL PROCEDURE OF ELECTRO-VIBRATORY MASSAGE

For example, let us take a hypertrophied inferior turbinated body of the left side of a patient, to operate on, the physician must be fitted out with a proper plant, viz , a first class induction machine, capable of giving no less than from 4,000 to 6,000 interruptions per minute or more I use generally 10,000 to 15,000, produced by the Engelmann or author's interrupter

Electrodes of different diameters and curves These are the chief instruments for the proper carrying out of this form of vibration The patient is seated before a reflecting mirror, with the head in a comfortable position A speculum must be used in order to apply the electrode over the body or tissue to be treated When the electrode is once placed over the hypertrophic turbinated body, the current is slowly graduated in strength, with the high speed of interruption at once Allow the electrode to remain in one position over the tissue treated for the entire séance Do not reintroduce the electrode without stopping your current, or your patient will receive a shock, which is to be avoided but start as you began, by turning on the graduated or tolerant current with its high speed frequencies, each sitting to last from twelve to fifteen minutes and repeated daily, for the first week, and every other day after that

If the patient is sensitive about the nasal cavities, a 5 per cent solution of cocain is advisable Regarding the time in which cures are effected, that varies according to the extent of the hypertrophy Some are cured in from ten to twenty sittings, or from six to eight sittings Every case must be individualized No set rules can be laid down

It is best to start on the inferior turbinated tissue first, in order to give room to the traveling of electrodes All obstructions to the entrance of the electrode must be removed previously Some patients will be found very sensitive in the beginning, to the induced current This is also noticeable with all other forms of massage employed in this cavity The current travels the sensitive distributed nasal nerves which can not be avoided You will often find in the beginning of the first few seconds of treatment, the patient wishes to have the electrode withdrawn, but soon submits and thinks no more of it Should much resistance on part of the patient exist, cocain will relieve all reflexes

After each sitting, a strong solution of alum dissolved in albolen, or some other compound of its kind, is applied to the massaged parts and well rubbed in by means of a probe wound with cotton In children, where the inferior turbinated tissue is found, as a rule, hypertrophied, electro-vibratory massage has given the best account of itself

There are no contra indications for the use of this method I have used it in all forms of disease about the pharynx and nasal passage and recommend the same to my colleagues

The electrode, of which a cut is here given, is one of the many used for the application of this treatment In some cases it is admirable to use soft material, as sponge and cotton, fixed into a conducting holder

ELECTROLYSIS BY A CURRENT CONTROLLER FOR THE REDUCTION OF SPURS OF THE NASAL SEPTUM

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10, 1895

BY W E CASSELBERRY, M D
PROFESSOR OF THERAPEUTICS AND OF LARYNGOLOGY AND RHINOLOGY IN NORTHWESTERN UNIVERSITY MEDICAL SCHOOL (CHICAGO MEDICAL COLLEGE) LARYNGOLOGIST TO WESLEY HOSPITAL, ETC
CHICAGO

It is unnecessary to describe spurs or excrescences of the septum narium further than to say that they are outgrowths of cartilage or bone, or of both combined, which project from the septum into the lumen of the nostril, thereby causing obstruction to nasal respiration and drainage In size, contour and exact location they are of infinite variety and the symptoms which they produce vary correspondingly in nature and degree, being at times so grave as regards complete occlusion, deformity, pressure effects, and the induction of neuroses, as to demand removal by whatever means, and again occasioning merely a sense of inconvenience or annoyance Customarily, excrescences are removed by surgical means, by the knife, saw and drill, and these methods are still to be indorsed for the majority of cases In skillful hands they are more rapid, more precise, and in the case of large bony spurs, it would seem, more effective than is electrolysis But the surgical method is sanguinary, and while many patients bleed but little, a considerable number suffer from profuse and troublesome hemorrhage and there is no way of telling in advance which ones will bleed, or when they will bleed Such cases usually demand packing of the nostril, either at once by the operator or by any accessible physician, if the hemorrhage occur later, as during the following evening or night, and the packing if not done with antiseptic material can lead to infection of the middle ear and this in turn to suppuration in the mastoid process

It is true that both profuse hemorrhage and infection can be avoided with reasonable certainty by the insertion in all cases, immediately after the operation, of an antiseptic packing of iodoform gauze, or by the closed treatment of the nostril by the antiseptic method of Roe, either of which, however, subjects the patients to some inconvenience and annoyance and causes sensitive ones to interrupt business or seclude themselves for a day or two Neither the danger of possible hemorrhage nor the inconvenience of a tampon is comparable to the benefit conferred by the operation in a case of major degree, but they do seem disproportionate to the ends sought in many cases of minor degree For these reasons, others, as well as myself, have sought in electrolysis at least an occasional substitute for the knife

Concerning the physics of electrolysis, it is only necessary to state that it is a process of chemic dis integration of tissue under the influence of an electric current by which water and salts are separated into their component parts, oxygen and acids being attracted to the positive pole and hydrogen and the bases to the negative pole

A resumé of the previous literature of the application of electrolysis to the treatment of nasal spurs need be but brief, most of the publications have been in French, are recent, and have not been freely circulated in this country Miot[1], of Paris, was the originator in 1888, and following him Garel[2], of Lyons, reported his results in thirty cases, but my attention was first drawn to the method by Moure[3] at the Ninth International Medical Congress at Berlin in 1890, where he read an elaborate paper on the subject and described minutely the technique Moure and Bergonie[4] have since embodied their studies in a monograph published in Paris in 1892, and Moure[5] again in 1894, before the Eleventh International Medical Congress at Rome, discussed in a paper the "Comparison between Electrolysis and other Methods of Treatment for the Destruction of Deviations and Spurs of the Nasal Septum "

Moritz Schmidt in his book, *"Die Krankheiten der oberen Luftwege,"* published in 1894, confirms the efficacy of the method as advanced by the French operators, a significant fact which goes far toward removing the sense of skepticism with which the subject was first viewed in America Among others may be mentioned Peyrissac, Meyer and Heryng, all cited by Newcomb

Only two papers by American authors have come under my observation One by Newcomb[6] of New York, with a report of two cases and an excellent review of the bibliography and technique, the other by Ballenger[7] of Chicago, with a report of three cases

All of these operators have employed, as the source of the electricity, a primary galvanic battery of about 30 cells The supposed necessity for this troublesome and unreliable apparatus has prejudiced many against the electrolytic method Allowed to stand unused for a time, it is often found that the acid fumes have corroded the metallic parts and the battery fails to work, or the cups leak, or the liquid slops over, or it otherwise exhausts one's time and temper To obviate these annoyances would mean to enhance the utility and availability of the method by electrolysis, and I therefore present this preliminary report of the results which I have secured by the use of the Edison electric light circuit and the McIntosh current controller

The Edison current is characterized by the conditions best adapted to electrolysis, that is moderately high tension or voltage, the volt being the unit of electro motor force, and comparatively low current strength or amperage The Chicago Edison current has an E M F of 110 volts, or about double that of a battery of 50 Daniells cells, one Daniells cell being selected as the standard, having an E M F of 1 volt The amperage depends on the amount of resistance in the circuit and it is so reduced by the resistance of lamps, controller, and human tissues as to be measured in milliampères or thousandths of an ampere The current strength necessary for electrolysis of nasal spurs is from 15 to 25 milliampères, measured with the resistance of the spur in the circuit, and to supply this current from fifteen to twenty-five cells of a galvanic battery would ordinarily be used with a corresponding E M F of from 12 to 20 volts or more It is evident, therefore, that the Edison circuit, while correct in kind, is far too intense in degree and must be reduced

Mr Neiswanger, electrician to the McIntosh Battery & Optical Company, on request, has furnished the following description of the current-controller which I have used

> ' The controller works on the 'shunt' principle The machine circuit consists of a succession of coils, nineteen in all, joined in series and having a united resistance of 209 ohms The patient may be placed in a shunt to one or more coils The coils vary in size, but are so proportioned as to modify the voltage in tenths and hundredths The sliding contacts are arranged in two rows The one on the left is connected with the larger coils, and consequently each coil in this row divides the E M F in the machine circuit by ten The one on the right is connected with the other row of contacts, and each coil divides the E M F by one hundred The two rows may be used singly or together "

The accompanying diagram illustrates the essential parts of the instrument

To elucidate the controller is so constructed that if placed in direct connection with the 110 volt circuit, and the left-hand or decimal slide be advanced to 1, enough coil resistance is removed to secure a current intensity of 1 of 110 volts, equal to 11 volts In like manner, if advanced to 2, 2 of 110 volts is secured, equal to 22 volts If, now, the right-hand or centesimal slide be advanced to any given contact, say 4, there will be added 04 of 110 volts, or 4 volts, equal now to 26 volts

The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION Nov 10 1894

But the decimal division of an initial 110 volt circuit is still too painful on advancing the contacts, so I have resorted to the expedient of placing a 16 candle electric lamp in the circuit ("in series") the resistance of which reduces the original E M F, aside from the action of the controller, to an initial current of 55 volts, or sometimes of placing two lamps in series in the circuit which reduces the initial current to 27 volts

The result is that, with one lamp in the circuit, on advancing the decimal slide of the controller to 1, enough coil resistance is removed to secure a current of 1 of 55 volts, or advancing to 2, 2 of 55 volts, equal to 11 volts And on advancing the centesimal slide, there will be added at each successive coil contact 01, 02, 03 or 04 of the initial 55 volts, or if stopping at 4, equal to 2 volts, which added to the 11 volts of the decimal slide, makes in all 13 volts This is the arrangement of the mechanism with which I have treated most of my cases

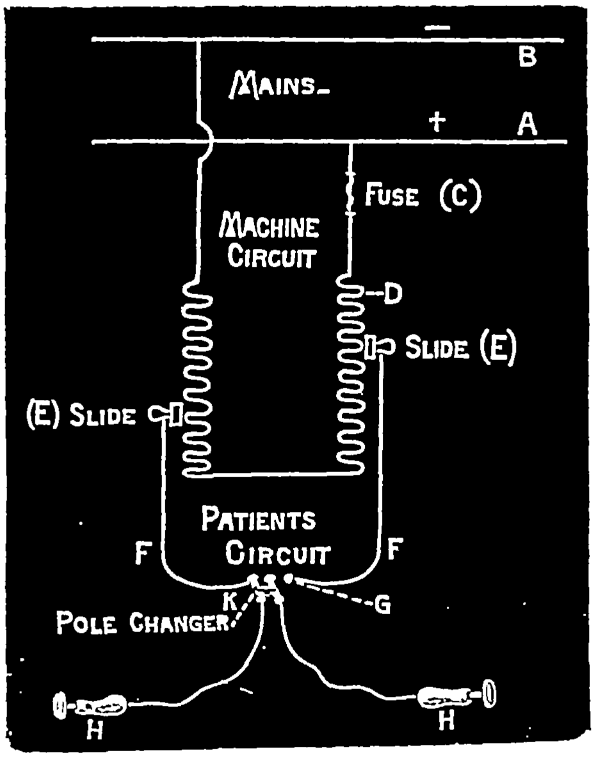

Fig 1

In one case herewith reported, I placed two 16 candle lamps, in series, in the circuit, which reduced the initial electro motor force with which the controller had to start, to 27 volts, and with the advance of the decimal slide to 1, 2 and 3, each point represented 1 of 27 volts, and each successive contact of the centesimal slide an addition of 01 of 27 volts In this manner a finer subdivision of the voltage is made and, possibly, less shock occasioned as the contact is moved from coil to coil

The lamp must be placed "in series" and not "in multiple," Figs 2 and 3 The degree of reduction in the E M F, when thus placed, was accurately determined by means of a volt meter

The controller has been constructed and has been thoroughly tested with a view to absolute safety A fusible wire that burns out when the current exceeds 500 m a is placed in the machine circuit, the supports for this fuse being two inches apart, it is impossible for the largest commercial currents to "arc" across, or jump from post to post In addition, connected with the Edison circuit to which I attach the controller are two fusible plugs, one in the house and one on the street, which serve to protect the Edison mechanism against the results of accidental connection, when grounded, of their own and other more highly charged wires, e g, arc lighting and trolley wires Moreover, the one or two 110 volt lamps which are placed in the circuit to reduce the initial voltage would serve as additional safety appliances against the largest commercial currents, for they would be burned out, and being arranged in series, the circuit would then be interrupted Any or all of these, it would seem, would prevent anything like a fatal charge ever accidentally reaching the patient, but the main reliance against what might prove a painful shock is placed on the controller fuse itself, which I am assured is of delicate and accurate construction. Mr Neiswanger, of the McIntosh Battery & Optical Co, states that he made the following tests before an assembly of physicians and electricians at Rochester

1 One thousand seven hundred volt alternating current, three fuses preceded the controller, of which the first two burned out on making the contact

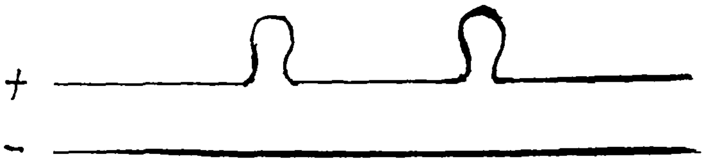

Fig 2—Lamps "in series"

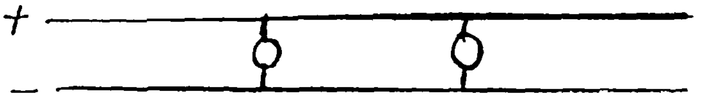

Fig 3—Lamps "in multiple"

2 One thousand seven hundred volt current, one fuse preceded the controller, both it and the controller fuse burned out

3 One thousand seven hundred volt current connected directly with the controller, both sponge electrodes held in one hand, fuse burned out instantly without communicating any charge to the experimenter

The character and arrangement of the needles still presents a fruitful field for the labors of those especially possessed of mechanical abilities Two methods are in vogue, the monopolar and the bipolar, although the latter is now preferred by Moure and his followers By the monopolar method, a single needle attached to one pole, preferably the positive according to Moure, and the negative according to Garel, is inserted into the spur, while a large plate electrode of chamois, constituting the negative pole, is held on some indifferent portion of the body, as between the shoulder blades or on the upper arm

By the bipolar method, two needles, one representing the positive and the other the negative pole, are both inserted into the spur, so that the current passes only from one needle to the other within the tissue to be destroyed, although the spur for a short space on all sides of the immediate area of insertion will be affected by the electrolytic action The needles which I have used in the cases herewith reported are made of irido platinum and are soldered to light parallel copper bars, fashioned like a galvano cautery electrode, for insertion into a cautery handle I have not, however, used a handle, but fastened the instrument directly to the conducting cords for the sake of lightness and easier adjustment The needle tips are 8 m m in length, 2 m m apart, and are quite thin They are in fact rather delicate and too short for the larger spurs, so I have had constructed a heavier and longer pair made of irido-platinum, mounted in a similar manner and attached straight, to a delicate handle These needles are nearly as stiff and hard as steel and have almost, perhaps not quite, an equal penetrating power They are about 20 m m in length (Fig 4)

The needles, instead of being permanently fixed parallel with each other, might be attached to separate holders and then introduced, each at any desired point in the spur, but this arrangement is awkward At times it might be desirable to have one or both needles slightly curved, in order to more closely follow the contour of a curved excrescence If parallel needles are used, they may be inserted either perpendicularly or horizontally, or at any angle between these positions, whichever conforms best to the shape of the spur

Moure employs ordinary sewing or sailmaker's needles of steel, regarding the oxidation of the positive needle, when of steel, as immaterial if a new one be used at each treatment Not being able to secure a satisfactory adjustable needle holder which would carry two points, I have used needles of platinum, hardened by admixture with iridium, which not being oxidizable, can be permanently soldered to a delicate holder and are then always ready for immediate use

It is the consensus of opinion that the bipolar method is equally efficient and less painful and troublesome than the monopolar, and also that with the bipolar method not more than two needle tips, one representing each pole, should be used

Case 1—Mr W M , medical student, is under treatment for hypertrophic rhinitis, and has also an excrescence from the base of the cartilaginous part of the septum, not of large size but which materially diminishes the lumen of the nostril

Feb 22, 1895, electrolysis by means of the Edison current and McIntosh current controller, one 16 candle lamp in the circuit Bipolar method with irido-platinum needles 8 mm (⅓ in) in length, attached in a single holder 2 mm apart The decimal slide of the current controller was pushed to 1, and the needles were then inserted into the anterior segment of the spur The slide was then advanced to 2, which equals a current of 11 volts, the milliampère meter registering 15 milliampères , ebullition of gas , crackling sounds , not painful The current was then increased by pushing the centesimal slide gradually to 4=18 volts registering 17 milliampères Now painful but tolerable Continued seven minutes The needles were then withdrawn and re-inserted one half inch farther back in the posterior segment of the spur and the process exactly repeated for seven minutes One drop of blood only on withdrawing the needles the first time

March 1 He reported having suffered no discomfort from the treatment

March 14 The slough has not yet separated

March 26 Result very satisfactory, the spur having disappeared, all except an insignificant remnant close to the nasal floor

Remarks—This was an experimental case The excrescence was of small dimensions and chiefly cartilaginous I might not have deemed it necessary to interfere with it by the surgical method, yet the patient is much improved by its reduction The slough did not separate, as a whole, but seemed to liquefy, and be in part discharged and in part absorbed without complete destruction of the mucous membrane, which has therefore been reproduced in the process of cicatrization more perfectly than is usual after the cutting operation This is an advantage as the tendency to incrustation, so frequently observed after the surgical method, due to the poor quality of reproduced mucosa will be avoided It is an advantage, however, which does not invariably follow electrolysis, since if the slough produced be large it will separate as a whole, with corresponding complete destruction of the surface mucosa

Case 2—Mr A G M , has been under treatment for hypertrophic rhinitis and adenoid vegetations which are now remedied He still complains of inability to breathe through the right side of his nose which disturbs his sleep The cartilaginous septum is deflected to the right and, in addition, situated toward the base of the convexity is an excrescence which projects sufficiently forward to approach the partially collapsed ala and so close the nostril By the removal of the excrescence without interference with the deflection, enough space could be gained for comfortable respiration The patient is of a nervous disposition and slight operative measures cause him involuntarily to flinch so badly that the surgical method might involve unusual difficulties

February 23 Electrolysis by means of the Edison current and McIntosh current controller, one 16-candle lamp in the circuit The same needles were used as in Case 1, being inserted 8 mm into the anterior segment of the spur for eight minutes, then withdrawn and re-inserted the same distance behind, into the next adjoining segment of the spur for six minutes With each insertion the decimal slide was advanced to 2, and the centesimal slide to 8, which equals about 18 volts, the milliampère meter registering at different moments from 15 to 25 milliampères Pain was felt only on making the contacts, chiefly on increasing the decimal slide from 1 to 2 A whitish discoloration, shading off to blue, was observed around the needles, and thus guided, an inspection of the opposite side was maintained in order to guard against ultimate perforation

March 11 The slough from the previous treatment has separated leaving a large concavity with projecting edges back and front of it which must be removed Electrolysis to the anterior edge, care being taken not to perforate because the needles, superficially inserted, are nearly opposite the point of greatest concavity Therefore a current of much less intensity, E M F , 7.5 volts, 7 milliampères was applied for seven minutes Result satisfactory

March 29 Electrolysis to the posterior edge or segment, the same quantity of electricity as at the first sitting being used

April 9 Final result entirely satisfactory, the excrescence having been removed quite as perfectly as if it had been done by the surgical method.

Remarks—The treatment was unusually tedious in this case, three sittings being required because unusual care was necessary not to produce a perforation by too extensive an effect at any one time It has been asserted as a disadvantage, that perforation is especially liable to result from electrolysis This case satisfied me that it could be avoided by proper care in any case in which it would be avoidable by the surgical method

Case 3 for the sake of brevity will not be recorded in detail Mr M J H , age 25 suffered from pulmonary tuberculosis in a state of arrest, but he complained at this time of nasal obstruction due to an excrescence of the kind which begins anteriorly and runs upward and backward, following the sutural line of the vomer and cartilaginous plate of the sep-

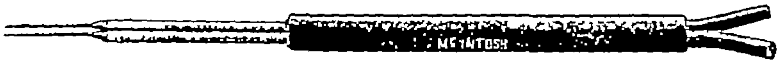

Fig 4 —Author's Needles

tum and terminating opposite the middle turbinal Both cartilage and bone entered into its composition and the result of electrolytic treatment was fairly satisfactory, the spur being very much reduced in prominence but not wholly removed The reduction in volume of the spur was probably commensurate with the proportion of cartilage contained in it

Case 4 was less successful Mr E R, aged about 19 years, has been under treatment for hypertrophic rhinitis, adenoid vegetations and hypertrophy of the tonsils, which are now remedied He has also a septal spur of the kind which begins anteriorly and runs upward and backward, terminating opposite, and projecting into, the middle meatus of the right side Likewise a smaller chiefly cartilaginous excrescence on the left side, anteriorly at the base of the septum

March 20 Electrolysis to the spur of the right side, 11 volts, 20 milliampères for four minutes, when the patient so nearly fainted that it was necessary to discontinue the treatment The needles would not penetrate thoroughly into the spur, the bone seemingly being of ivory hardness

March 22 Electrolysis to the smaller cartilaginous excrescence on the left side, 11 volts, 12 milliampères for five minutes, the patient again complaining of faintness and pain the treatment was abbreviated

April 22 The larger spur is practically unchanged, the smaller cartilaginous one has disappeared but the space has not yet entirely healed

April 27 Electrolysis again attempted on the larger spur, the heavier needles for greater penetrating power, and the method with two lamps in the circuit for the more gradual application of the current being selected This treatment was also a failure for the needles could not be made to penetrate adequately, and beside the patient nearly fainted after three minutes of a current of only 8 volts and 10 milliampères

Remarks —This case demonstrates that the electrolytic method has its limitations As one would expect, difficulty will be encountered in inserting the needles into those spurs and ledges which are composed largely of bone of ivory-like hardness, which would seem to limit the method in its greatest degree of usefulness to excrescences which are composed mainly of cartilage, or to those of bone in which it will suffice to remove the cartilaginous surface, together with whatever of adjoining bone can be influenced without inserting the needles directly through hard bone itself However, the cases of spur from the nasal septum for which the electrolytic method of reduction *is* applicable are very many and with the efficiency, convenience and compactness of the McIntosh current controller which adapts the Edison electric circuit to its use, I consider it a valuable addition to our resources Still other cases are under treatment, the result of which additional experience will be communicated at an early date in another paper

Venetian Building

TREATMENT OF PELVIC PUS CASES BY ABDOMINAL SECTION—REPORT OF SIXTY-SIX CASES, WITH REMARKS

BY J WESLEY BOVÉE, M D

WASHINGTON D C

In this resumé of my work in abdominal section for the relief of various suppurating diseases in the female pelvis, whatever I may offer as deductions is given for what it is worth Previous to 1891 this class of surgery was little known in this city and, I might almost say, not at all practiced So that four years practically covers the amount of time over which ranges the experience of Washington abdominal surgeons in celiotomy in cases of pelvic pus

A large majority of the series have been operated upon in the presence of quite a large number of medical students and physicians, and have been in the free wards of Columbia and Providence Hospitals From the nature of the environments of such patients, their general condition is usually very bad Add to this, the effects of such devitalizing pathologic conditions, as are noted in another part of this report, and you will easily understand how feeble is the framework upon which we hope to effect a regeneration I am very certain that a number of patients who were saved by operation, would have soon died had nonsurgical treatment alone been employed I am more positive of this, because of certain other cases that were admitted to the hospitals and died before operation In this belief I know that I am antagonizing the statement of the lamented Goodell, "that very rarely will these pus cases die if not operated upon" During my service at Columbia Hospital for Women, have been admitted cases I have considered too weak for operation the day of admission, I have directed the resident physician to prepare them next day for operation, provided they were living, and they have died in the meantime Other cases have refused to submit to operation and have died within a short time outside

These cases have led me to appreciate how near the life margin were a number of those in this report before operation You will, therefore, readily understand that a series of such cases does not indicate a series of selected cases operated upon for a fine record rather than saving of endangered lives Had I been jealous of my record, I could easily have declined operation in some cases that died afterward In fact, seven of my mortality list were cases that were considered far more liable to die than to recover

My first case of this kind was done March 17, 1891 It was a puerperal case, delivered in Columbia Hospital Puerperal septicemia followed and a large abscess in the abdomen was detected High fever and a rapid feeble pulse with other dangerous symptoms being present, abdominal section was done the forty-second day after labor By the hospital people it was thought she would die with or without an operation, and I afterward learned the hospital superintendent engaged a special nurse for two days, expecting the patient to live no longer than that The uterine wall had been bored through on the left side just above the ovarian ligament, the cavity of the Fallopian tube had become a part of the abscess cavity, which extended nearly to the spleen and was separated from the intestines by a great mass of exudate The abscess sac was removed and the uterine wound cleaned and sutured She made an excellent recovery and is now robust and well This was, I believe, the first case of the kind successfully operated on in this city Twice since, have I operated (Cases 3 and 29) in cases of puerperal septicemia in which putrid infection was present, both patients dying I believe this variety of cases is the worst the abdominal surgeon has to deal with As it is considered a fatal condition, the saving of even a small percentage of cases of puerperal putrid infection by celiotomy should be considered quite successful When you open a women's abdomen and find the broad ligament, lymphatics, intestines and other adjacent structures saturated with pus, as was one of my cases, you can not but realize how little we can do to prevent a fatal termination But we must hope to find most puerperal septic cases in a more favorable condition In the very bad cases I am not sure that abdominal surgery is advisable I am convinced cases like No 3 should not be subjected to operation In this *case, the ovaries were large free* pus sacs, the Fallopian tubes apparently normal, and the lymphatics between the ovaries and uterus, great pus channels The autopsy revealed the uterus,kidneys and intestines riddled with pus Case 29 lived two weeks and died twenty-four hours after a hurried second operation which revealed the posterior wall of the uterus entirely sloughed away and the intestinal wall reservoirs of pus This pus is highly infectious and the patient rapidly succumbs to the poison

I have done no simple exploratory operation in pus cases and have never abandoned a case As a result, the number of deaths from operation is greater than it otherwise would be The question of leaving an appendage in suitable cases has been presented to me in a practical manner but a few times, double disease being present in nearly every case I have when possible, left an ovary, or a portion of one, that the menopause might not be brought upon the patient suddenly while she is recuperating from the depression of vitality due to disease and suppuration The patient does not feel unsexed if menstruation continues

The right appendage, has in a large majority of my cases, been the most severely diseased, and very often I found the vermiform appendage so intimately adhered to a right suppurating mass as to require its removal In a few cases it was slightly adhered to the uterus or Fallopian tube and not removed

Pyosalpinx on both sides occurred in thirty cases, and on one side only, in seventeen cases, making forty-seven cases, or 71 per cent of the series in which pyosalpinx, technically speaking, was present Pus was present in the tube, however, in sixty-five cases Double tubo-ovarian abscess was found nine times and in twelve cases this condition was on one side only—much more frequently than I had supposed it is found

Ovarian abscess was found in fifteen cases, being double four times

Deaths —The mortality rate of all cases was 16 per cent Case 2 was a very bad one and would, perhaps, have died had the most skilled abdominal surgeon done the operation Owing to lack of experience my conception of the pelvic conditions may have been exaggerated and possibly I would now successfully operate in similar condition She survived the operation but five hours, dying from shock

Cases 3 and 29 have been previously mentioned as suffering from putrid infection Case 10, tubo ovarian abscess and broad ligament cyst of the opposite side has already been referred to She took ether badly, the pulse was 150 as the operation was about to begin It was considered a temporary effect of ether and the operation proceeded Strychnia and brandy were generously given hypodermically during the fifty minutes the operation consumed The cyst was principally on the right side, though it had lifted up the peritoneal coat of the uterus entirely and dipped down into the left broad ligament and Douglas pouch It contained three quarts of clear fluid and was not entirely removed A left tubo-ovarian abscess, badly adhered, was removed Her pulse was 180 at the finish and the patient continued in shock until her death, thirty-three hours later

Case 12, hydrosalpinx and pyosalpinx The adhesions in this case were such as are seldom found When anesthetized the appearance of the abdomen reminded one of a uterine fibroid reaching nearly *to the umbilicus This proved to be a hydrosalpinx,* formidably adhered and very large Its enucleation was an exceedingly difficult task and led to severe bowel tears A Fallopian tube containing six ounces of pus was removed from the opposite side I erred in stopping to suture the intestinal wounds, as the operation was thus prolonged to ninety minutes and the patient did not react from the shock before her death seventeen hours later

Number 14, had had a criminal abortion performed and the removal of double tubo-ovarian abscess was followed by panic The patient clamored to go home and declared she would die if kept in the hospital Despite these features of the case I expected her to recover She suddenly expired, however, on the third day after an effort to get out of bed She probably died from embolism

Case 21 was one of double pyosalpinx and a right ovarian abscess containing four ounces of foul-smelling pus, a bad case with general adhesions The operation required thirty minutes and a drainage tube was used three days Until the ninth day she progressed as favorably as any patient could be expected During that day she had a severe pain in the region from which the ovarian abscess was removed Suspecting bowel adhesions to be the cause, salines and other remedies were administered, but the bowels did not respond satisfactorily, the abdomen was meteoric, the intensity of the pain continually increased and her expression was anxious On the fifteenth day vomiting, not stercoraceous, set in and that afternoon I reopened the abdomen and found three loops of small intestines fastened by general adhesions into the right half of the pelvic cavity The amount of adhesions that had formed in fifteen days in spite of salines and other drainage was remarkable The intestines were liberated and punctured to allow escape of gases She was flushed out with normal salt solution and a hot rectal enema of salt Epson salt and whisky administered She lived about thirty minutes When vomiting began, I realized I had postponed the second operation too long, but tried to make amends by operating even at that late stage

Case 35 was an emergency case, a prostitute and opium habitué, suffering with intestinal obstruction, almost constant stercoraceous vomiting and an abdomen filled with pus The next morning after entering Providence Hospital I saw her and urged abdominal section which she absolutely refused She decided to go to Baltimore next day, a trip I knew she could not possibly take, and she was given morphia in large doses That night a telephone message from the hospital announced her desire for operation The following morning her condition was such that an operation seemed cruel Nevertheless I opened the abdomen under ether As soon as the peritoneum was incised about six ounces of pus escaped The intestines and omentum were separated from the inferior surface of an ovarian abscess extending nearly to the liver From the character of adhesions, I suspected a dermoid cyst It was aspirated, but as this process seemed too slow, a Tait's trocar was used to empty it of about three quarts of horribly offensive pus A ruptured pyosalpinx was found and removed and another containing four ounces of pus was removed from the other side Nearly a gallon of pus was removed from this patient The operation was hurried, but the patient died a few minutes after its completion During the operation she seemed likely to die at any minute and I did not expect her to be taken from the table alive I have since learned she had had an abortion about four weeks before the operation

Causes—I do not think that social condition and age have much bearing upon the etiology of these conditions, except that puberty and the menopause usually limit the time Then, too, so long as otherwise respectable women resort to criminal abortion to rid themselves of prospective trouble incident to child-bearing and child-caring, they, as well as the various species of prostitutes, will be liable to pelvic suppurative inflammations The relative number of cases due to gonorrhea is thus far speculative A diagnosis by staining or cultures can hardly be expected in gonorrheal pyosalpinx or ovarian abscess of long standing

Abortion is a frequent cause, as are various kinds of debauchery In fact, I believe many cases might be traced to these, could a correct history be procured I believe, however, that many cases of suppurative inflammation of women's tubes and ovaries are not due to sexual contact in any way, but rather to injuries from accidents, "taking cold" during a menstrual epoch or unusual hard work and exposure Add to these a debilitated condition and we have the true causes of many cases While gonorrhea lurks, for long periods of time, in the uterine mucosa, we often have endometritis in the virgin and it may easily extend to the Fallopian tubes, causing under favoring circumstances a purulent inflammation

Anesthetics—To produce anesthesia, ether alone was used in fifty-two cases, chloroform alone in two, and chloroform followed by ether, or *vice versa* twelve times Where no contra-indications to either anesthetic exist, I prefer to begin with chloroform and if operation extends beyond thirty minutes, to substitute ether at the expiration of that time For prolonged anesthesia I prefer ether I am led to believe that the danger of producing renal hyperemia by anesthetics extends to the employment of chloroform Case 64 was one in point

Rupture of pus sacs during removal is a dangerous complication of celiotomy and should be studiously avoided In weak patients the fight against disease germs by the peritoneum will be made easier for our patients, by preventing the leakage among the pelvic and abdominal viscera, that often follows such ruptures We should be constantly on our guard to do so Unfortunately we can not often prevent such rupture from taking place We can, however, usually wall these pus collections off from the surrounding structures by gauze plaques, thus preventing contamination Of course, there are many cases of sterile pus, but how are we to be sure of such conditions previous to the attempt at removal In thirty-four of my cases, rupture occurred

Adhesions were present in sixty-four cases and were very bad in forty-nine Great care is necessary in dealing with them The posture of Trendelenburg is undoubtedly of great assistance in separating bowel adhesions, as well as in checking hemorrhage from vessels of considerable size In employing this auxiliary we should bear in mind that the abdominal viscera is placed nearly under the diseased pelvic structures, and leakage of pus among the intestines is thus facilitated Nor should we lose sight of the fact that quite large vessels may be left open during enucleation in this position, only slight bleeding occurring, and when the horizontal position is resumed severe hemorrhage follows It is probably best not to use this position beyond fifteen minutes Great care is necessary to prevent injuries to the bowels in separating them from the masses to be removed This occurred in nineteen of my cases, in five of which the bowel wall was torn completely through, the wounds stitched and complete recovery followed. Many times the recovery of the patient is greatly imperiled by the delay incident to suturing a number of small tears in the outer coats of the bowels and in such cases it is often best not to prolong the operation to cover these surfaces

Hemorrhage from various causes often occurs during these operations In a few of my cases it was due to the slipping off of ligatures from large or too short pedicles In such cases it has been my practice to pick up the stumps of the ovarian and uterine arteries with artery forceps, whip stitch the cut surfaces of broad ligaments between them and then to ligate these vessels separately and stitch them together In patients of low vitality the loss of even a small amount of blood may endanger their lives In such cases the hypodermic injection of normal salt solution has been resorted to with great satisfaction In Case 33, severe hemorrhage occurred in a vein low in the broad ligament One pint of this solution was thrown into the bowel and the abdomen flushed with it During the following twenty-four hours she received, under the skin, a total amount of sixty-two ounces and made a good recovery Case 57 was given six and one-half pints We should avoid using too much at one time and placing too much in one place I have had small sloughs form from these causes When practicable, it should be injected into some medium-sized vein

The use of sterilized hot water or salt solution in flushing out the pelvic cavity was followed in sixty cases This is almost indispensable where pus has escaped during the operation or there is considerable oozing from adhesion wounds The stimulating effect of flushing was not found so valuable as had been supposed

Drainage—I am very partial to the use of the glass drainage tube It was employed in forty-one cases on an average of two days I believe the time-honored maxim "When in doubt, drain," is a safe one to follow, notwithstanding many abdominal surgeons consider its use as evidence of slovenly surgery Unless the nurse be well trained, however, the danger accompanying its use counterbalances its advantages. I did not use vaginal drainage in any case, as I consider it inferior to abdominal It is almost impossible to keep the vagina sterile We are only to remember the odor and discharge that comes from the wound in the top of the vagina a few days after vaginal hysterectomy, to appreciate the liability to infect the pelvic and abdominal cavities if an opening from the vagina into the peritoneal cavity be left for drainage The newly made track through the abdominal wall, it seems to me, should be much better

High temperature previous to operations was common In some cases it was high at the time of the operation In four cases that recovered, the temperature ranged from 103 to 106 degrees for several days previous to operation, and in three that died, it ranged equally as high

In such cases it was noticed that after the operation the temperature usually dropped rapidly the first day and, later, gradually to normal or thereabout A transient, slight rise often occurs after operation, even in cases that have been normal in that respect It is usually unimportant, being due to cathartics, stitch-hole abscesses or nervous irritation There must be something more than moderate fever to indicate danger

Additional Operations and Complications —In eight cases, endometritis was such a marked complication that curettement and packing of the uterus was done just before the abdomen was opened In Cases 21 and 29, both fatal, a second celiotomy was done

Intestinal obstruction was present in Case 21 after the first operation and in Case 35, making a primary operation imperative Abdominal fistulæ followed in three cases for various periods I may perhaps attribute to Dame Fortune the fact that, so far as I know, I have had in these sixty-six cases no pelvic hematocele or mass of exudate (other than three abdominal fistulæ cases), no fecal fistulæ, no ureteral injuries and no tear completely through the bladder wall Two cases of peritonitis occurred, Nos 21 (incident to intestinal obstruction) and 53

After Treatment —The patients are usually kept in bed twenty-one days and if any complications be present at the expiration of that time, their getting up is postponed Often if the patient is restless the first night after operation, one-twentieth to one-tenth of a grain of morphia is administered hypodermically, which relieves sufficiently pain and relaxes nerve tension to produce a night's sleep with the result of having a refreshed patient next morning This is a great gain in desperate cases where we look to the first two days' history as an indication of the ultimate result It is not sufficient to cause bowel paralysis The second day an attempt is made to move the bowels by salines and purgative enemata When this has been effected once or twice and the patient is little disturbed, our prognosis should be favorable, The use of strychnia both before and after operation, by the mouth and hypodermically, is of great value It is the best heart tonic and hypodermically is an excellent stimulant

The examination of urine is of the utmost importance before any severe surgical operation can be performed We can not be too particular about its condition It is not sufficient to have the specific gravity, reaction, and absence or presence of albumin in a given specimen We should know the amount voided in a full day, and in addition, too, the amount of urea and urates, also whether epithelium from kidneys or ureters is present We must ascertain whether the kidneys are acting well as eliminators, whether the *débris* of tissue waste is being carried off We must not be misled by a trace of albumin as the only pathologic ingredient, for it often comes from the vagina instead of the bladder Catheterized specimens are most reliable for examination A trace of albumin often occurs when large collections of pus are present

SIXTY SIX CASES IN WHICH CELIOTOMY WAS DONE FOR PELVIC PUS-FORMING DISEASES

Case 1 I M age 22 single puerperal septicemia tubo-utero abdominal abscess removal of left appendage and cornu of uterus March 17 1891 glass drainage three days recovered operation forty two days *after* delivery

Case 2 L F age 30, single putrid infection multiple abscesses removal of both appendages Feb 15, 1892 glass drainage died in sixty three hours

Case 3 Mrs —, age 30, married double pyosalpinx and double ovarian abscesses, removal of both appendages in pieces April 26, 1892, glass drainage died in five hours

Case 4, Mrs N age 30 married double pyosalpinx, removal of both appendages June 2 1892 no drainage recovered

Case 5 Mrs M, age 40 married double tubo-ovarian abscesses removal of both appendages Sept 14, 1892 glass drainage two days recovered

Case 6 I W age 23 married double tubo ovarian abscesses removal of both appendages April 22 1893, glass drainage two days recovered

Case 7, M W age 27 widow double tubo ovarian abscesses removal of both appendages May 18 1893, glass drainage three days recovered

Case 8, L D age 27, married double pyosalpinx and large pelvic hematocele, removal of both appendages and hematocele June 12 1893, glass drainage two days recovered

Case 9 S C age 34, single double pyosalpinx removal of both appendages June 10, 1893, no drainage recovered

Case 10, A R, age 42, married right broad ligament cyst and left tubo-ovarian abscess removal of both appendages and nearly all of cyst June 22 1893 glass drainage one day died in thirty three hours of shock

Case 11 Mrs M, age 32 married double tubo-ovarian abscess, removal of both appendages July 8 1893, glass drainage two days recovered

Case 12 A G age 22 single hydrosalpinx and pyosalpinx, removal o both appendages July 13 1893 glass drainage died of shock in seventeen hours a very bad case

Case 13 J L age 31 widow left tubo ovarian abscess and right pyosalpinx removal of diseased parts July 27 1893, glass drainage one day recovered

Case 14 A C age 25 married double tubo ovarian abscess, removal of both appendages August 29, 1893, glass drainage two days was panic *stricken* and died suddenly on third day

Case 15 Mrs M age 28 married double pyosalpinx removal of both appendages August 30 1893, no drainage recovered

Case 16 I D age 18 married left suppurating dermoid cyst of ovary and right tubo ovarian abscess removal of both appendages Sept 7 *1893* no drainage recovered

Case 17, M M age 26 widow left tubo ovarian abscess and right ovarian abscesses and pyosalpinx, removal of both appendages Sept 14 1893 gauze drainage a few days recovered

Case 18 S H age 23, married pyosalpinx and ovarian abscess, removal of both appendages Sept 25, 1893 no drainage recovered

Case 19 M W age 18 married double tubo ovarian abscess removal of both appendages Nov 9 1893 glass drainage one day gauze two days recovered

Case 20 K W age 27 married ovarian cyst and pyosalpinx removal of both appendages Nov 13 1893 no drainage recovered

Case 21 L G age 23 single ovarian abscess and double pyosalpinx removal of both appendages Nov 16 1893, glass drainage one day, gauze two days died on fifteenth day after second operation

Case 22 L J age 27, married left pyosalpinx and right utero tubo ovarian abscess, removal of both appendages Nov 20, 1893, glass drainage two days and gauze recovered

Case 23 C J age 30 married ovarian abscess and double pyosalpinx removal of both appendages Nov 23 1893 glass drainage two days recovered

Case 24 L B age 21, widow double tubo ovarian abscess removal of both appendages Dec 11, 1893 glass drainage one day recovered

Case 25, S S age 22 single double pyosalpinx removal of both appendages Dec 28 1893, no drainage recovered

Case 26, E S age 18 married double pyosalpinx, removal of both appendages Jan 8, 1894 no drainage recovered

Case 27 N S age 24 married double pyosalpinx removal of both appendages Jan 8, 1894, glass drainage one day, gauze two days recovered

Case 28, C A age 30 married pyosalpinx and tubo-ovarian abscess removal of both appendages Jan 18, 1894, glass drainage one day gauze two days recovered

Case 29 Mrs G age 35, married putrid infection removal of both appendages Jan 28 1894, glass drainage two days died in fourteen days after second operation

Case 30 Mrs H age 25 widow double tubo-ovarian abscess, removal of both appendages, Jan 29 1894 no drainage recovered

Case 31 L L, age 22 married double pyosalpinx and left ovarian abscess, removal of both appendages Feb 5 1894, no drainage recovered

Case 32 Miss K, age 26 single ovarian abscess and double pyosalpinx removal of both appendages Feb 5, 1894 no drainage recovered

Case 33 L A age 22 single large ovarian hematoma and double pyosalpinx removal of both appendages March 8 1894 no drainage recovered

Case 34 Miss M age 19, single double pyosalpinx removal of both appendages March 20 1894 no drainage, recovered

Case 35 Mrs S, age 32 married double pyosalpinx and ovarian abscess and intestinal obstruction removal of both appendages April 2 1894 glass drainage died in a few minutes nearly one gallon of pus removed

Case 36 Mrs G age 30, married multilocular ovarian cyst and double pyosalpinx removal of both appendages April 10 1894 glass drainage two days recovered

Case 37 Mrs D, age 38 married dermoid ovarian cyst ovarian cyst and double pyosalpinx removal of both appendages April 26 1894 no drainage recovered.

Case 38 Mrs M age 30 married ovarian cyst and pyosalpinx (pregnant) removal of both appendages May 17 1894 no drainage recovered delivered Dec 21 1894

Case 39 H D., age 25 widow double pyosalpinx removal of both appendages May 21, 1894 glass drainage one day recovered

Case 40 Mrs J age 23 single double pyosalpinx removal of both appendages May 28 1894 no drainage recovered.

Case 41 Miss M age 22 single ovarian abscess and double pyosalpinx removal of both appendages May 31 1894 no drainage recovered

Case 42 Julia B age 40 widow right ovarian cyst and left pyosalpinx removal of both appendages Aug 27 1894 no drainage recovered

Case 43 A H age 19 married double pyosalpinx removal of both appendages Sept 1 1894 no drainage recovered

Case 44 R. P age 31 married double pyosalpinx removal of both appendages Oct 17 1894, no drainage recovered

Case 45 H J age 20 single tubo ovarian abscess and ovarian cyst removal of both appendages Oct 25 1894 glass drainage two days recovered

Case 46 P age 32 widow omental dermoid cyst double ovarian abscess and right pyosalpinx removal of both appendages and dermoid Nov 5 1894 glass drainage two days recovered

Case 47, Mrs C, age 20 widow pyosalpinx and tubo ovarian abscess removal of both appendages Nov 28, 1894, glass drainage two days, recovered

Case 48, V T, age 30, single right pyosalpinx, removal of diseased part Dec 20, 1894, glass drainage two days, recovered

Case 49, L F, age 19 single, ovarian abscess and double pyosalpinx, removal of both appendages Jan 14, 1895, glass drainage two days, recovered

Case 50, M F, age 22, single left parovarian cyst and right pyosalpinx, removal of both appendages Jan 20, 1895, no drainage recovered

Case 51, Mrs D, age 21, married ovarian abscess and double pyo salpinx, Jan 28, 1895, glass drainage two days, recovered, curetted May 20, 1895

Case 52, Mrs W, age 27, married tubo ovarian abscess and salpingitis, removal of both appendages Jan 31, 1895, glass drainage three days, recovered

Case 53, H, age 19 widow double pyosalpinx, left ovarian abscess and endometritis, removal of both appendages and endometrium March 10 1895, glass drainage died acute septic peritonitis

Case 54 M G, age 25, single, double pyosalpinx and double ovarian abscess, removal of both appendages March 10, 1895, no drainage, recovered

Case 55, A P, age 35, single double pyosalpinx and double ovarian cysts and uterine fibroids, removal of both appendages March 14, 1895, no drainage, recovered

Case 56, M S age 33 married double tubo ovarian abscess, removal of both appendages March 21 1895, glass drainage thirty two hours, recovered left abscess contained twenty ounces of pus

Case 57, H, age 25 married, pyosalpinx, ruptured tubal pregnancy and endometritis, removal of both appendages and endometrium March 23, 1895, glass drainage thirty six hours, recovered, septic infection due to attempted criminal abortion

Case 58 J B, age 27, single, pyosalpinx and tubo ovarian abscess, removal of both appendages April 7, 1895 glass drainage recovered

Case 59, J W, age 38, married pyosalpinx and pelvic abscess, removal of both appendages April 15, 1895, glass drainage, died of shock, nineteen hours later mitral regurgitation

Case 60, Mrs S age 23, married, double pyosalpinx, ovarian abscess, ovarian cyst and endometritis, removal of both appendages and endo metrium May 1, 1895, glass drainage two days, recovered

Case 61, I S, age 23 single pyosalpinx and tubo ovarian abscess, removal of both appendages May 4, 1895, glass drainage thirty six hours, recovered septic, case emaciated

Case 62, C M, age 21 single double pyosalpinx and ovarian cyst, removal of both appendages May 13 1895 glass drainage two days, recovered

Case 63 L J age 21, single pyosalpinx and tubo ovarian abscess removal of both appendages May 22, 1895 glass drainage one day, recovered

Case 64, M B, age 24 married double pyosalpinx, removal of both appendages May 30, 1895, glass drainage died in twenty two hours, autopsy showed one kidney useless and the other acutely congested, suppression of urine

Case 65, L M age 18 single, double pyosalpinx and ovarian abscess removal of both appendages June 6, 1895, glass drainage one day, recovered, bowel badly torn

Case 66, L D, age 21, single double pyosalpinx, removal of both appendages June 17, 1895, no drainage, recovered

---

IS THIS LEPROSY?

PRESENTATION OF TWO CASES

Read before the Fiftieth Annual Meeting of the Ohio State Society at Columbus, Ohio, May 16 1895

BY T C McDOUGAL, M D

NEW LEXINGTON, OHIO

I am glad that I am able to present these two very interesting cases for your examination, for the unusual circumstances under which they have developed render it important that a correct diagnosis be made, and to that end only do I direct my present inquiry and solicit your every aid

Hannah M Garey first came under my observation in December, 1894, when she was examined by the New Lexington Pension Board Drs P A Gordon and G W Clemson participated in the examination She had applied for pension as a dependent child of Geo W Garey, a deceased soldier of the 187th Regiment Ohio Infantry, and at that time she presented the following manifestations of a disease we diagnosed as anesthetic leprosy the left hand and lower forearm were swollen and rather firmly thickened, the hand and wrist being about twice the normal size The distal phalanges were all lost, except from the little finger and thumb, and the stumps were all healed The thumb nail was deformed and discolored The hand was being amputated at the radio-carpal articulation by a narrow, encircling, ulcerative process, and the work was so near completion that only the ulnar vessels and some of the tendons remained Both surfaces were covered by granulations, were bathed with extremely foul-smelling pus and were yet held in close apposition, except at the bordering skin, where some retraction had taken place in the healing process which had begun.

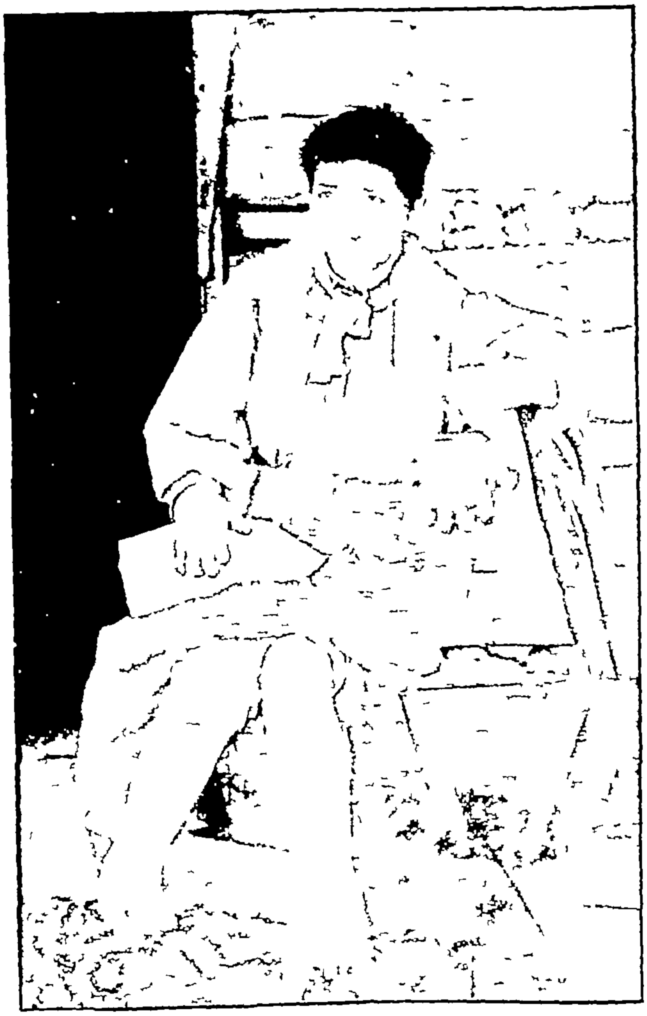
The right hand and fingers were somewhat swollen and clubbed and all the distal phalanges except those of the little finger and thumb were lost The wrist joint was somewhat deformed because of an unnatural prominence of the head of the ulna on the dorsal side Both feet were swollen and thickened and this condition also involved, to some extent, the legs, being more marked in the left From the left foot the first and second toes were entirely lost, the third toe was off at the proximal phalangeal joint and the fifth toe all lost On the plantar surface of stump of great toe was a thick dark crust covering an unhealed ulcer In the middle of the left sole was an ulcer the size of a silver half dollar which reached deep into the foot, and from which there came a very offensive discharge From the right foot the great toe was lost, the second and third were off at middle of proximal phalanx and the fourth was pointed upward so that it was considerably out of line with the others The little toe was not affected, except that it was involved in the general thickening of the foot All the affected members were more or less anesthetic, the thermal anesthesia being especially marked

There was a blister, the size of a silver quarter, on the back of right arm just above the olecranon The end of the tongue had been destroyed by ulcerations that had healed, the left side of lower lip and both wings of nose had suffered loss from the same cause and were consequently deformed, and the lower jaw had likewise suffered loss of bone, teeth and gum. Her eyes looked weak and blinking and her vision was poor

She is 18 years of age and this malady began to manifest itself, so her mother states, by abscess formations in her legs when she was about fifteen months old In two or three years the toes began to ulcerate and come off, and then the hands became involved The flesh ulcerated from the fingers leaving the blackened dry bones exposed, and these she persistently drummed on the tables and chairs until her mother cut them off with shears She menstruated moderately regularly from the time she was 14 years of age until one year ago, when menses ceased. The plantar ulcer had been a perforating one, so that when the mother used poultices—as she did—on the top of the foot they would run through, unless the foot rested on something to stop the plantar opening

January 18 of this year, I saw her again in company with Dr McTeague At that time she was sweating freely, though the house was cold, and her pulse was accelerated She complained of pain in neck and left leg from which she had been suffering much Her mother said she had lately fallen several times, limp and motionless, and that she had been having some sort of choking spells The hand was still further separated so that it hung downward when the arm was raised On the back of the hand was an extensive gangrenous blister, due to the pressure of splints used to hold the hand in position The epidermis covering the remainder of the hand had been recently shed, and replaced by the formation of new The blister on elbow had healed, and the skin marking its location was papery and harsh and completely insentient to touch or pain The plantar ulcer was healing, and covered by a thick, black, offensive crust

I next saw her February 15, 1895 At this time there was a large ulcer, with sharply defined edge, on the back of hand, corresponding in size and location to the blister seen on former visit Since my previous visit there had appeared for the first time in the history of the case—so far as we were able to learn—an eruption on the left side of neck and on the front of left leg The eruptive spots were not raised, were dark yellowish brown in color on the leg and darker on the neck They were thickly set and made with the surrounding skin a dappled appearance, which shows fairly well on the leg in the photograph Since the appearance of the eruption there have been no choking or fainting spells The plantar ulcer, after a duration of about five years, was now healed At this time the negatives were obtained from which the photographs were made, and the hand was removed and sent away for bacteriologic examination



Her younger sister Hattie is 8 years of age, and has been afflicted for about three years Her feet are clubbed and legs stocky The great toe of left foot is off at middle of proximal phalanx There is a dark crust on lower part of stump The distal phalanx of second toe is lost The right great toe is like the left The nail is lost from second toe and the ulcer which was present on the top of toe—as you can see in the photographs is now healed The little toe has been entirely destroyed and a healthy stump remains There is some anesthesia of feet and legs There was a moderately indurated swelling on outer front side of leg just above the ankle, which has almost disappeared

The hands, you see, are also affected They are thickened and chubby The thumb nails show evidence of disease The ends of index fingers are off and here an apology for nails is offered in the existence of small, dark, horny thickenings on the centers of ends of fingers On the radial side of the wrist the skin is rough, and here are a number of small wart-like elevations You will notice a number of blisters on the palmar surfaces of her hands These are accounted for by the fact that she is fond of parching corn in a skillet on the cookstove and her touch can not appreciate a destructive degree of heat, and consequently her hands are frequently burned You have seen that she is unable to appreciate any difference between the feeling of a bottle filled with hot, and another filled with cold water Her eyes are red and tearful Her voice is coarse and croaks, and she has a croupy cough at night

Both girls have suffered at times from painful nerves, and when deep abscesses formed, or when amputations began in the bones they suffered from them But the ulcerations, though reaching deep into the tissues or even destroying a member, have not been painful

Hannah walked with little discomfort on the plantar ulcer, and during the later stages of the destructive process that robbed her of her hand she suffered none, and laughed when it was being cut away

The mother insists that these ulcerations are always the result of some accidental injury They sometimes heal kindly after a variable duration, and sometimes go on to complete destruction of the part

These sisters have never been outside the State of Ohio Both parents and all the grandparents were natives of Ohio and belonged to healthy long-lived families The parents were married in 1866 There are eight children and all are healthy except Hannah the fourth born, and Hattie the last born The mother is 44 years old, and healthy The father was pensioned for sunstroke He is reported as having died of some brain trouble March 10, 1893 He had an offensive discharge from the nose and an eruption on upper lip and end of nose This trouble developed shortly after marriage and was never recovered from Physicians, who had treated him for it, called it catarrh and eczema The 187th Regiment Ohio Infantry, of which he was a member was stationed during the few months it was in service at Nashville, Tenn , and at Dalton, Kingston and Macon, Georgia

This is about all of practical importance I know, concerning these unfortunates Then let us see "where we are at," and whether or not the probabilities are that a mistake has been made in attributing lepra as the cause of all these manifestations

The most comprehensive discussion on the subject of leprosy I have found, is given by Prince A Morrow in his system of Genito-Urinary Diseases, Syphilology and Dermatology It contains the apparent truth of all I have been able to read on this subject

For the purpose of comparison, permit me to recite here the most prominent and distinguishing symptoms of the anesthetic form of leprosy as given by him the phenomena are essentially those of multiple neuritis, consisting principally of disorders of sensation and nutrition The first cutaneous manifestations of nerve leprosy are usually in the form of bullæ or erythematous spots They may not appear, however, for years later, and they may even fail altogether Analgesia and thermo-anesthesia may be present with or without impairment of the tactile sense Most of the cutaneous lesions encountered in nerve leprosy, before the mutilating stage sets in, are due to the blunted sensibility The deadened nerves give no warning through the perception of pain of the inroads of heat, cold, or other external source of injury A patient often receives severe injury as a scald or burn, unconsciously, or a pin may be thrust into the flesh without causing pain Sensibility to puncture, however, is variable, not only in different parts of the body but in contiguous spots, the same is true of sensitiveness to temperature There are frequent phenomena of disassociation Some have no perception of cold, but feel heat, and *vice versa* There is also slowness in the transmission of sensation Although the most frequent sites of the spots are the legs about the ankles, they may be found on the backs of the arms and shoulders, the elbows, the back, the abdomen, the nates and the face, they are rarely seen on the palms and soles, and never on the scalp Another form of eruptive lesion is the pemphigoid The blebs are always located more particularly on the hands and feet, on the posterior surface of the elbows and the anterior surface of the knees Many years may pass and the patient with the exception of an occasional innocuous eruption or neuralgic pain, may have no disorder of sufficient importance to awaken his suspicions as to the exceeding gravity of the disease with which he is afflicted Pemphigus blebs locate on the phalangeal articulations and ulcerate, uncovering the deeper tissues, whose consecutive disease leads to the elimination of the bone and to extensive mutilations

One of the most characteristic lesions is the so-called plantar ulcer, which is especially liable to occur in patients who habitually go barefoot The bones of the fingers and toes may be lost without ulceration by a process of osseous absorption affecting one phalanx after another, or the phalanges may become the seat of gangrene, which extends until a mark of demarkation is found and the member is spontaneously amputated The reparative process is usually prompt and complete, the stump healing perfectly, when the loss of the phalanges is only partial, the stumps may stand out at every conceivable angle, and often in the most distorted positions

Now, by the light of this symptomatology—the most prominent landmarks given on the subject, let us look at these cases Even though they have not true leprosy they suffer some disease so nearly like it in all its apparel of symptoms as to afford me ample apology for choosing the inquiry I did as the subject of my paper I certainly have never seen a single case of typhoid fever that corresponded more closely in its symptomatology to the classical description of that disease than do these cases to the descriptions I read of anesthetic leprosy

It would seem superfluous in this connection to consider eruptive diseases of the erythematous type, and the various pigmentary affections of the skin which may simulate the earlier stages of leprosy, but in which mutilations, sensory disorders or marked nutritional changes do not occur, and so would it seem superfluous to exclude by differential diagnosis those ulcerative or mutilating diseases whose evolution is unattended by dysesthesia or other disturbances of sensation, nor yet would I feel justified in occupying time in excluding diseases of the nervous system attended with disturbances of sensation, but which are not accompanied by mutilations Such diseases may furnish one or more symptoms analogous to one or more of the symptoms encountered in the evolution of leprosy, but it is far more difficult to find points of resemblance between them and the disease here manifested, than points of difference

Reynaud's disease or symmetrical gangrene is, we think, excluded by the fact that anesthesia is limited to the ischemic or cyanotic spots about to become gangrenous, and the gangrene is usually limited to a small area of the pulps of the fingers, or fingers and toes, extensive mutilations do not occur, and a peculiar characteristic of Reynaud's disease is the symmetrical distribution of the local symptoms, whether situated upon the trunk or extremities

Morvan's disease or syringomyelia (*identical*) may bear a most deceptive resemblance to nerve leprosy that has developed only in the upper extremities But syringomyelia may be excluded in these cases by the single fact that it never affects the lower extremities

I received a copy of the report of the bacteriologic examination of a portion of the amputated hand, which I will read

Treasury Department, Office of the Supervising Surgeon-General, Marine-Hospital Service
Washington, D C, March 28 1895

To the Supervising Surgeon General, U S Marine Hospital Service

Sir —I have the honor to make the following report on a specimen from a supposed case of leprosy, submitted for examination by Dr C O Probst, Secretary of the Ohio State Board of Health

The specimen presented for examination is a portion of the left hand, including the little and ring fingers The entire member is thickened to about twice its natural size

On the dorsum of the hand is an extensive superficial ulcer with sharply defined and irregular margin At the wrist, the ulceration has extended deeply through the tissues, amputating the hand at this point A similar process seems to have affected the tip of the ring finger

Sections were made and studied from several different places Four were taken from the edge of the ulcer, two from its center, and one through the skin and thickened subcutaneous tissue, including the nerve going to the little finger

All the sections disclosed a general hypertrophy of the parts and a large overgrowth of connective tissue Some of the specimens from the edge of the ulcer showed the histology of the specific granulomata A thickening of the blood vessel walls was noticed in the subcutaneous tissue

All the sections were stained for lepra bacilli, with negative results Those sections containing giant cells were also stained for tubercle bacilli None were found

The disease, therefore, in my opinion is neither leprosy nor tuberculosis, which, by exclusion, throws some weight upon the suspicion of syphilis Very respectfully,

(Signed) M J Rosenau, P A Surgeon, M H S

Respectfully forwarded to the Supervising Surgeon-General

(Signed) J J Kinyoun, P A Surgeon, M H S

(Copy)

As granulomata occur in the new tissue growths of leprosy and also in tuberculosis, as well as in syphilis, we do not understand the report to state the specific granulomata to be pathognomonic of syphilis

Because no lepra or tubercle bacilli were found, he concludes the disease is neither leprosy or tuberculosis, and therefore must be syphilis

Relative to this, I again quote Morrow (New York

Medical Journal, July 27, 1889) who says "The bacillus is not found in the chronic sores or necrosed tissues and bones of the anesthetic leper Numerous and repeated examinations of sections of an amputated finger showed no bacilli " The same author in his text-book published in 1894—only last year—states with his first sentence on the diagnosis of the anesthetic form of leprosy "While the identification of the lepra bacillus in the tissues is rarely practicable in nerve leprosy, yet the invariable presence of, anesthesia in established cases constitutes a diagnostic element of almost pathognomonic value" And similar statements are made by other authors Did not, therefore, our esteemed bacteriologist go beyond the pale of scientific knowledge in expressing this opinion, and into the realm of speculation in concluding it was therefore syphilis?

I think that we have in these cases such a history and combination of symptoms as have never been approached in any case of syphilis any of you have ever seen in practice, or have ever read in a report It is true the father had a disease of the nose which, so far as the description we have of it goes, might have been syphilis, lupus, or some other disease But as the first symptom of leprosy is so often an affection of the nose we think we are justified, in the light of these subsequent developments, in our impression that it was of leprous character, and that somebody, somewhere and at some time, probably in the sunny South during the war, communicated to him this leprous malady, and that he is the source from which came this wreckage Admitting that syphilis might show itself by such unprecedented manifestations in a single case, it multiplies the improbabilities a hundred fold that two such unusual cases should occur together and be alike—for considering the difference in duration they are as nearly alike as two cases of any disease usually are If this be syphilis, is it inherited or acquired? If inherited, how did the other children escape it? There are three children older than Hannah, and three between Hannah and Hattie who are healthy, evidently free from any taint, as is also the mother If acquired, again I ask why should all but two escape, for syphilis is many times more contagious than leprosy? The mother, more endangered than the rest, would almost certainly have contracted it

It must be admitted that there is much to be said in favor of the view that these cases are actually lepra We have the spontaneous amputations in both the upper and lower extremities, the plantar ulcer, the dysesthesia, the pemphigoid eruption on back of elbow with its resultant anesthetic scar, the thick, black, hard offensive crusts that form on the ulcerous sores, the distorted direction of the toes, the ulcerations of the nose and mouth, the weak eyes and peculiar voice, and the eruptive colorations It is the exception and not the rule that so many evidences of the disease are found Moses, of old, would have dealt with them as lepers on the discovery of far fewer and less characteristic symptoms than these, and without his camp would their habitation have been

If I have wearied you with a paper of too great length, I have done so because impressed with the practical importance of the subject For there is no doubt but that leprosy is on the increase, not only in other countries, but also in our own If what I have shown you is leprosy, let us do what we can to set aside all ignorant fear of the malady In the face of a disease which has for ages been accounted one of the most dreadful of plagues, it is not surprising that the public should be stricken with panic On the other hand, let us profit by the experience of the past and urge the adoption of measures that will be certain to prevent its spread If what you have here seen is not leprosy, let us free these people from the odium of such suspicion If it is syphilis, let us cure it And if neither, let us find out, if possible, what the disease is that has thus wrecked the life of one, and so threatens another with the same fate, and in which decomposition, by such a frightful anticipation, has wrought its work without waiting for the grave

---

STATE PROVISION FOR EPILEPTICS

Read before the Medical Society of Virginia, Sept 4, 1895

BY WILLIAM FRANCIS DREWRY, M D

FIRST ASSISTANT PHYSICIAN CENTRAL STATE HOSPITAL MEMBER AMERICAN MEDICO PSYCHOLOGICAL ASSOCIATION AMERICAN MEDICAL ASSOCIATION MEDICAL SOCIETY OF VIRGINIA ETC
PETERSBURG, VA

The purpose of this paper is to direct attention to that neglected and abandoned class of defectives, known as epileptics, and I plead from the standpoint of physician, humanitarian and political economist, for a betterment of their condition It is, however, beyond my power to convey in written words, a proper idea of the abject wretchedness of many of these unfortunates I hope others may be convinced, as I have been, that no other afflicted beings are in such urgent need of special institutions for their care and treatment

Epilepsy is to the physician, the statistician and the sociologist, alike, an unknown and unknowable factor As a concomitant of idiocy,[1] insanity and crime,[2] this blight upon the human race assumes enormous proportions

PROGNOSIS

The etiology and pathology[3] of epilepsy being so little understood, the treatment must be more or less empirical However pessimistic it may seem, the prognosis of the disease, so far as permanent recovery is concerned, is seldom favorable[4] No disease is more intractable to therapeutic measures alone The larger one's experience with it becomes, the deeper this conviction is fixed Few chronic diseases, however, are more amenable to improvement, provided judicious treatment, prophylactic, medical and moral, is faithfully carried out The insidiousness of its inception, the subtlety of its progress, its practicable incurability, its hereditary nature, its demoralizing effects, combine to make it one of the most dreaded maladies And, in the language of Sachs "The frequent development of dementia, idiocy or of epileptic insanity, in epileptics, makes the outlook gloomier still "

PREVALENCE OF EPILEPSY

It is certainly a very widespread disorder No accurate data can be procured upon which to estimate the proportion of epileptics to the general population For obvious reasons, little reliance can be placed on the census reports In this country the usually accepted ratio is 2 per 1,000 of the population Some authorities, however, think it is much greater than that[5] One hundred and thirty five thousand epileptics[6] What an enormous army of unfortunates distributed throughout our land, a great majority of whom are in a more or less helpless con-of this great colony are to "provide gratuitously the humane, curative, scientific and economical treatment and care of dependent sane epileptics" It is thought that this institution will in a few years become self-supporting

The last Legislature of Massachusetts, just and generous, authorized the establishment and maintenance at the public expense of a hospital home for epileptics

The hospital cottage at Baldwinsville,[16] Mass, though a private benevolent institution for non-insane epileptic children, receives a liberal donation from the State

In California,[17] Pennsylvania,[18] Maryland,[19] Minnesota and Michigan,[20] limited provision, on the industrial and educational plan, has been made at the respective State institutions for the feeble-minded, for the care of sane epileptics Illinois, Wisconsin and other States are being urged by their respective medical societies and boards of charities to erect separate institutions for epileptics

VIRGINIA'S DUTY TO HER DEPENDENT EPILEPTICS

Will Virginia, upon whose soil was erected the first hospital on this continent exclusively for the care of the insane, and who built the first and still has the largest asylum for insane negroes in the world, be any longer derelict in her duty to her poor epileptics? Will she refuse to respond to the cry of these unfortunates? I believe not

The State care of epileptics is a subject worthy of the most serious and earnest thought and is of the deepest interest to all the people Whether this care should consist in a hospital, pure and simple, or a colony on the plan I have outlined, or whether special accommodation should be provided at institutions for other defectives—the insane or the feeble-minded—are questions for mature consideration

SUGGESTIONS

In an article published in the *Virginia Medical Monthly*, September, 1894—"Care of Epileptics on the Colony Plan,"—I advocated the State care of all dependent epileptics, in an institution exclusively for them I reiterate the opinion expressed in that paper, viz, that a farm-colony, conducted on the industrial and educational plan and provided with every facility for the most scientific medical treatment of the patients, as sketched in the foregoing pages, would meet the requirements better than any other method yet suggested *It is feasible, it is economical, it is humane It has been tried elsewhere and demonstrated beyond question to be a practical success*

Who should reap the benefits of such an institution?

1 The epileptics now confined in the hospitals for the insane By removing these, 200 in number, sufficient room would be gained at the institutions to accommodate probably all the insane of the State in need of care and treatment, at least for a year or two

2 All the epileptics now in the county and city poorhouses—certainly as many as 200

3 Dependent sane epileptics, each county and city to have at the colony a number of patients proportioned to its population

4 A limited number of pay patients, probably, who may be in pressing need of special treatment and care

5 Both white and colored epileptics—separate and distinct provision being made for each race

To determine the question of epilepsy, proper legal proceedings should be had as in the cases of insanity The State, however, is sadly in need of a better law regarding the commitment of the insane

THE DUTY OF PHYSICIANS

Our lawmakers need to be reminded of the necessity and humaneness of special provision for epileptics Let us, Fellows of the Medical Society of Virginia, with a broad and comprehensive devotion to the general good and to individual happiness, use our best efforts in the creation of a just public sentiment regarding this matter and, as far as lies in our power, try to "raise the fallen, cheer the faint and heal the broken-hearted" Public sentiment, the potent power that accomplishes great deeds of mercy and benevolence, never arrays itself against the afflicted and suffering Only the ignoramus or the narrow-minded bigot will dare discourage any effort to help such unfortunates If there be any such, tell them the old proverb "Whoso stoppeth his ears at the cry of the poor, he also shall cry himself, but shall not be heard"

It is not, I believe, Utopian to hope that in the near future our State will awaken to a recognition of her duty to her epileptics, and see the wisdom of making that provision for them which is clearly demanded by every consideration of justice, equity and philanthropy †

---

† Immediately after the reading of the above paper, some discussion took place and the following resolution was offered and unanimously adopted

"*Resolved*, That it is the sense of the Medical Society of Virginia that the State should make some special provision for its dependent epileptics

"*Resolved*, That an epileptic institution (or colony), conducted on the industrial plan, commends itself to this society

"*Resolved*, That a committee of five be appointed by the Chair, two of whom shall be the present President (Dr R J Preston) of this society and the author of the paper (Dr William F Drewry), who shall present this matter to the next Legislature of Virginia and try to induce that body to give it that attention it justly deserves

REFERENCES

[1] Dr E A Osborne, Superintendent of the California Institution for the Feeble Minded, is authority for the statement that in his experience, epilepsy exists as a predisposing or complicating cause of feeble mindedness in over 60 per cent of all cases [Institution Bulletin, Feb 1, 1891, page 18] Mr Miller, Superintendent Nebraska Asylum for Feeble Minded says he believes that epilepsy in some form permanently enfeebles more minds than all other complications [*Charitable Observer*, Jan 1, 1894]

[2] According to Richter, most crimes, especially murder, burglary, common theft, embezzlement, resistance of State power, come by epileptics or in those with a tendency to epilepsy [A MacDonald in "Abnormal Man" October, 1893 pages 51 and 77]

[3] Hirt, in his admirable book on 'Diseases of Nervous System," says "The structure as well as the physiologic functions of the human brain are, up to the present time, so little understood that we are far from having any sure basis upon which to lay the foundations of a cerebral pathology Epilepsy is a fundamental neurosis the seat of which is still unknown"

[4] The best authorities, Peterson among them, think that no more than 3 per cent of idiopathic epilepsy in general practice get well Sachs has seen but very few cases of absolute cure of genuine epilepsy

[5] Osborne and others

[6] Peterson thinks that the proportion of insane epileptics to the sane epileptics is very small, much less than 10 per cent [JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Sept 30, 1893]

[9] In an admirable paper on the "Provisions for Epileptics" read at the National Conference of Charities and Correction, 1894 Hon W P Letchworth, of the New York State Board of Charities, said that there are charity workers whether medical or lay, who have found it almost impossible to obtain employment for those who suffer from fits, with the result that the workhouses, alms houses, and lunatic asylums become the only places where these unfortunate people can be received

[10] It has been repeatedly stated by writers that Handel the great musician, Dostojewsky, the author of "The Idiot," Petrarch, the poet and writer Napoleon Bonaparte and Julius Cæsar, the renowned soldiers Mahomet the Prophet, St Paul, the great apostle, and the erratic Byron were all sufferers from this "thorn in the flesh"

[11] Rev John Bost a Lutheran preacher was the name of this great benefactor His institution is still in a flourishing state and reflects much credit upon its creative genius

[12] Von Bodelschwingh, a Protestant pastor, started his institution in Westphalia with one cottage and a garden, and twelve patients

[13] Dr William Alexander, aided by the liberality of a wealthy citizen of England, established in 1889, the Maghull Home near Liverpool, where a limited number of epileptics receive care and treatment in accordance with the most advanced theories The results of this praiseworthy movement have been so gratifying that efforts are being made to enlarge its capacity

In Surrey, the Countess of Meath, prompted by her generous and benevolent spirit has established a pleasant refuge, having a capacity for about fifty, for epileptic girls and women

In London there are one or two hospitals where recent cases of epilepsy are received or given special treatment

The National Society for the Employment of Epileptics has purchased a farm in Buckinghamshire, upon which there are in course of erection suitable cottages to accommodate several hundred (eight hundred I think) sane epileptics Separate provision will be made for adult males, adult females and children Here will be provided "a home for those necessitous epileptics who are able and willing to work but for whom their friends are unable to procure employment on account of the affliction which bars their admission into ordinary fields of industry"

[14] In 1892 there was built at Wilhelmsro in Sweden the nucleus of a home for epileptic children The methods adopted there are those in vogue in La Force, France

[15] There is only one State hospital exclusively for epileptics in this country—the one at Gallipolis Ohio In 1890 a bill favorable to the establishment of a hospital for epileptics was passed by the Ohio Legislature The corner stone was laid Nov 12 1891 To General Brinkerhoff President of the State Board of Charities, belongs the greatest credit for this noble charity, for he was untiring in his efforts to get the authorities to recognize the wants of the epileptics of his State

[16] This was the first charity institution for epileptics in this country It was opened in 1882 as a private benevolent establishment with nine patients Now there are more than one hundred little sufferers domiciled there

[17] About one hundred epileptic children are cared for in the Home for the Feeble Minded The able Superintendent, Dr Osborne writes that "the demand for admission of epileptics has been steady, persistent and far in excess of our means to provide for their care"

[18] The St Clement s Hospital for the care of indigent sane epileptics of Philadelphia maintained chiefly by private donations has been in existence for three or four years and is doing a good work on a small scale Steps are now being taken looking to the ' organization of a colony farm convenient to Philadelphia on which can be erected necessary buildings, including an infirmary, workshops and separate small cottages wherein the patients according to their mental and physical conditions can be cared for in the most approved manner"

At the Elwyn School for Feeble Minded about one hundred epileptic children are being cared for in a separate building The State Lunacy Commission in 1893 urged the Legislature to make separate suitable accommodation for epileptics, upon an industrial basis

[19] The Maryland Institution for Feeble Minded will soon erect a building especially for poor epileptics Under the auspices of the King s Daughters a small farm colony for epileptics is being conducted near the city of Baltimore

[20] Michigan has begun the erection of farm cottages for her epileptics and feeble-minded, to be conducted on the industrial plan

Surgeon-General Sternberg's Annual Report

The Report of the Surgeon General of the Army for the year ending June 30, 1895, presents a statement of the disbursements made from various appropriations and then discusses matters of interest to the Medical Department The following is a synopsis of the report

Medical and Hospital Supplies—During the past year a new edition of the Supply Table of the Medical Department was issued, in which such changes were made as seemed called for by the progress of medical science Medical and surgical chests issued some years ago for field service were refitted and modified in their arrangement as suggested by experience in their use Recently published medical works were sent to military posts with the view of keeping medical officers informed of current advances in medicine and surgery The old system of weights and measures has been disused and the metric system substituted The use of the latter was made obligatory on medical officers from Jan 1, 1895 Post surgeons have been directed to set aside in their hospitals a special room as an operating room, or when necessary to submit estimates for the construction of such a room The necessary appliances for fitting up these operating rooms in accordance with the requirements of modern aseptic surgery will be provided With a similar end in view the supply department is issuing iron bedside tables with non absorbing tops of heavy glass for use in the wards

During the year a board of officers was convened by me to investigate and report on the form of litter found to be best suited for Army use having in view economy, simplicity of construction, durability, lightness and adaptability for the services required This board devised a new model which differs from that formerly accepted in weighing only seventeen instead of twenty four pounds The slings accompanying it are simple and detachable It is considered that this new litter will simplify the litter drill and not only lessen the burden of the bearers, but contribute materially to the comfort and safe carriage of those who have to be transported by them

Library—There were presented to the library during the year 517 books and 7,792 pamphlets and journals Total number of books now in the library, 117,263, of pamphlets, 193,031 Volume XVI of the Index Catalogue includes from "W" to "Zythus" and forms a volume of 1,104 pages It completes the first series of this work The manuscript of volume I, new series, is nearly ready for the printer, the usual appropriation having been made for this volume

Army Medical Museum—The total number of specimens in the museum at the end of the fiscal year was 32,889, of which 623 were received during the year The museum was visited during the year by 52,094 persons

Army and Navy General Hospital, Hot Springs, Ark—The officers' division contains 16 beds, the average occupancy of each for the year being only 120 days The greatest number of officers under treatment at one time was 10 The men's division contains 64 beds Eighty-four men were treated during the year 33 of whom continued under treatment at its close Of the 51 completed cases, after deducting 6 known to have been discharged at their posts later, the percentage of recoveries was 70 6 Pulmonary cases are not improved by treatment at this hospital

Medical Officers—There were 98 medical officers reported as having been on duty with scouting parties and on other field service during the year

Promotions during the year Two deputy surgeons general with the rank of lieutenant colonel, to be assistant surgeons-general with the rank of colonel, two surgeons with the rank of major, to be deputy surgeons general with the rank of lieutenant colonel, two assistant surgeons with the rank of captain, to be surgeons with the rank of major, eight assistant surgeons with the rank of first lieutenant, to be assistant surgeons with the rank of captain Deaths none Retirements one assistant surgeon general with the rank of colonel one assistant surgeon with the rank of captain, for disability

Army Medical Examining Boards were convened for the examination of officers for promotion to the grades of assistant surgeon with the rank of captain and surgeon with the rank of major, but no board was necessary for the examination of candidates for position in the Medical Department of the Army as the number of assistant surgeons in service had not been reduced to 110, the number allowed by the Army Appropriation Bill for the year ending June 30, 1894.

Hospital Corps—The character of the *personnel* has improved Great care is taken to investigate the character and previous record of every man offering for enlistment, reënlistment or transfer from the line with a view to maintain a high standard of sobriety and efficiency A considerable reduction in the number of privates has taken place during the year, owing to the abandonment of a number of military posts On June 30, 1895 there were only 530 privates as compared with 585 at the end of the preceding year No examination for appointment as hospital steward was held during the year as the number of stewards available for assignment from discontinued posts rendered such examination unnecessary, nor is it probable that an examination for the position of hospital steward will be held during the current year Thirty-three candidates for assignment as acting hospital steward were examined in October, 1894 Twenty three were found qualified and have since been detailed, ten failed to pass Owing to the greater number of casualties in the corps of acting hospital stewards it is probable that an examination for a few vacancies will be held during the coming fall

The companies of the Hospital Corps at Fort Riley, Kansas, and Washington Barracks D C, not only afford opportunities for instruction which can not be given at the posts, but serve as depots from which men can be drawn in emergency to supply the needs of active service This advantage was particularly shown in the railroad riots of the year

Examination of Recruits—The number of applicants for enlistment and reënlistment during the year was 16,586, white 15 625, negro 911, Indian 50 Of these 7,481, or 45 1 per cent were accepted, including 44 4 per cent of the white, 54 8 per cent of the negroes and 94 per cent of the Indians Of the whites 51 4 per cent were rejected while 4.2 declined enlistment, of the negroes 43 2 were rejected and 2 per cent declined Diseases of the eye caused the rejection of 7 77 per cent of the applicants, under weight and imperfect physique 11 46, minority 1 43, general unfitness and undesirable 3 13, bad or doubtful character or unsatisfactory references 3 14 imperfect knowledge of the English language 1 66, illiteracy 0 67

In every thousand of the accepted recruits there were 927 whites, 66 7 negroes and 6 3 Indians, and of the 927 whites 607 8 were natives of the United States 94 64 of Ireland 94.24 of Germany 31 68 of England, 16 97 of Canada 15 50 of Sweden 11 89 of Denmark and 11 23 of Austria The average age of the whole number was 26 8 years The average height was 67 38 inches, that of the native American 67 50, of the foreign born 67 18, of the negroes 67 21 The average weight was 145 88 pounds, native whites 145 06, foreign born 146 77, negroes 149 19 The expansibility of the chest was from 34 27 to 37 17 inches, native whites 34 08 to 36 99, foreign born 34 63 to 37 57, negroes 34 25 to 36 83

Identification of Deserters —From January 2 to August 17, 1895, the whole number of identifications was 66, including 8 cases of men who had left the service The 66 represented the "repeating" element of 2,493 recruits whose outline-cards had been examined i e, of every thousand recruits enlisted from civil life 26 47 were identified through the outline card records as deserters, military convicts or otherwise bad characters

Health of the Army —The health record of the Army for the calendar year, 1894, is a most satisfactory one Taken as a whole, it may be said to be the best annual record ever consolidated from returns sent in by U S Army medical officers, for although the death rate is a fraction higher than the lowest rate ever recorded, the other rates are by far lower than they have ever been before in the history of our Army The number of admissions per thousand of mean strength was only 1,089 73 as compared with 1,289 04 during the calendar year 1893, and with 1 376 89 the average of the years of the previous decade The rate of admission for injuries was as large as usual, but the reduction in the number of cases of disease was most gratifying, the admission rate having been only 845 42 per thousand of strength as compared with 1,048 01 and 1,121 06 respectively for the previous year and the years of the previous decade The rate of non efficiency or constant sickness was only 34 49, contrasting favorably with former reports, 40 15 in previous year and 42 51 as the average of the previous ten years, and the average number of days lost on account of disability by each man of the Army was only 12 6 as against 14 7 in 1893 and 15 5 in the previous ten years That this reduction in the sick rates was not effected by the discharge of sick men on certificates of disability is readily seen, for the number of men so discharged was less than in any previous year, 13 30 per thousand of strength including 2.89 for injuries, as against 14 93 in 1893 and 26 48 as the average annual rate of the ten years immediately preceding The lessened rates can be attributed only to the greater care in the selection of recruits and in the preservation of the men from insanitary influences subsequent to their enlistment

The death rate from all causes was 6 69 per thousand of strength as against 6 91 and 8 22 for the previous year and decade The death rate from injury was 2 13, so that the rate from disease was 4 55 as compared with 4 01 of the previous year, 3 95 of the year 1889 the lowest recorded rate for disease, and 5 64 the average rate of the years of the previous decade

Infectious diseases, general and local, gave an admission rate of 273 51, or one-fourth of total admissions, while causing one third of the non-efficiency, showing in this that although the rates have been much reduced this year there is considerable room for improvement by the suppression of infec tion To the high rate of these infections, venereal diseases contributed 80 43 per thousand of strength, while malarial diseases gave only 74 72, a notable fall from 114 50, the average of the previous ten years Injuries took second place as causes of admission with a rate of 244 21, diseases of the digestive system third, with 237 23, and of the respiratory system fourth, with 79 76

As disabling factors the general and local infections were most prominent, causing 12 07 of the Army rate of non-efficiency, 5 03 of this was due to venereal affections, and only 1 88 to malarial infections The constant disability due to injuries was equal to 7 88 per thousand of strength

The absolute number of discharges for disability was 368 as compared with 413 in 1893 Eighty of these were caused by injury, 49 by diseases of the nervous system 44 by consumption, 43 by diseases of the locomotor system, 86 by venereal disease, and 34 by diseases of the organs of special sense

The deaths numbered 185 as compared with 191 in the previous year Fifty nine of these were due to accidents, 49 to infectious diseases, general and local, 20 of these were due to typhoid fever and 17 to consumption, diseases of the nervous system 24, of the respiratory organs 19, of the circulatory system 15 Eight deaths were caused by alcohol and its direct results

The mean strength of the Army during the year according to medical reports was whites 22,904, negroes 2,086, Indians 386, total 25,376 The admission rate of the negro troops was considerably less than that of the white soldiers, 811 60 as compared with 1,116 44, and this lower rate was due to the relative freedom from disease, for their admission rate for injury was as *high* as that of the white troops Their number constantly sick was 25 93 per thousand while the corresponding rate among the whites was 35 18, and the average number of days lost by each on account of sickness or injury was respectively 9 5 and 12 8 The rate for discharge also was lower among the negroes, 9 40 as compared with 13 56 among the white troops There was little difference in the death rate of the two races This is the most favorable showing yet made by the statistics of sickness among the colored troops of our Army

The number of Indians was so small that it is unnecessary to dwell on their statistics Their death rate was exceedingly high, 20 27 per thousand, due as in previous years to consumption, pneumonia and injuries

Health of the Military Departments —The admission rates of the military departments varied from 713 49 per thousand of strength in the Department of Columbia to 1,470 94 in the Department of Texas The light sick rate of the negro troops mentioned above, was particularly marked in the Departments of Dakota and the Colorado, where the admission rates were only 656 31 and 665 63 respectively In the Department of the Platte, on the contrary, the negro admission rate, 1211 12, was higher than the Army average In Texas, which had the highest admission rate, and in the Columbia which had the lowest, there were no negro troops The two departments last named had also the highest and the lowest rates of non efficiency or constant sickness, 50 27 and 23 56 daily sick per thousand of strength The Departments of Dakota and California had 28 79 and 30 68, the rates of the other departments did not differ much from that of the Army as a whole The death rates varied from 4 80 in the Department of the Colorado to 13 99 in Texas In the Departments of Dakota and California the death rates were lower than the average of the Army, 6 69, in the other departments they were higher The rate of discharge for disability was lowest, 6 76, in the Department of the Platte, and highest, 24 22, in the Department of Texas In the others it did not vary much from the average The Department of Columbia had the best record for the year, the Department of Texas the worst

The Highest and Lowest Rates at Individual Posts —As noted in summarizing the statistics of sickness in the military departments, the post of Key West Barracks had the highes admission rate, 2,226 89 per thousand of strength This pos was reestablished in 1893, during which year its rate was bu slightly in excess of that of the Army The high rate of th past year was due to an epidemic of dengue Only tw other posts had the admission rate for the year in excess o two entries per man of the average strength, Camp Eagl Pass and Fort Myer During the previous year no less tha ten posts had such excessive rates and among them wer three of the largest in the country, Columbus, Jefferson Bar racks and Davids Island Columbus Barracks had the high est rate of non efficiency, 66 66 per thousand of strengt This, however, must be considered as a great improvemen in the record of this station as, in the five years immediatel preceding, its rates varied from 71 98 to 92 74 Three othe posts had more than 6 per cent of their strength constantl sick, Key West Barracks, Camp Eagle Pass and Fort Har cock The first in 1893 had a rate but slightly larger tha the average of the Army, but the others have always ha high rates Among the larger posts, Fort Custer, Va couver Barracks, Fort McPherson and Madison Barracks ha the lowest admission rates during the year, and among th smaller posts, Forts Mason and Trumbull Fort Custer an Madison Barracks had the smallest rates of non efficienc among the larger posts The constant sickness at the fir named was less than 1 per cent Forts Yellowstone, Trun bull, Stanton, Canby and Mason had the best records in th respect among the smaller posts

Diphtheria —At Fort Yates, sixteen cases were reporte from the old and crowded infantry barracks, while the me in the light and roomy cavalry barracks were exemp Every year for several years back, diphtheria of a dead type has visited one or more of the families of enlisted me at West Point, N Y This year has proved no exception one family the mother and six children were affected, o of the latter died on the morning after medical attendan was called in In another family four children were affecte Of these eleven cases, ten recovered under treatment antitoxin

Typhoid Fever —During the calendar year 152 cases, which 20 were fatal, were reported This does not diff from previous annual reports Fort Sam Houston had cases Fort Sheridan 24, Fort Leavenworth 11 Regarding the disputed question as to the nature of the fever sometimes reported as "Texas fever," Major L M Maus has contributed a study of the cases at Fort Sam Houston which leads him to the conclusion that the fever so reported is an atypical enteric fever A case of this Fort Sam Houston fever imported into Fort Clark was studied by Major H S Kilbourne and shown to be one in which enteric fever was complicated with malarial infection Captain W B Banister reports the fevers at Fort McIntosh as enteric The reports of these medical officers are of interest and value

Anthrax—Lieutenant C C McCulloch furnished reports of two cases of this rare and fatal disease in the human subject The persons affected were civilians in Rio Grande city

Diarrheal Diseases were not unusually prevalent Camp Eagle Pass and Forts Hancock and Clark had the highest rates The cases at the last mentioned post were complicated with malarial infection

Malarial Diseases—The admission rate was 74 72, as compared with 93 64 in 1893, and 114 50 the average annual rate of the preceding decade Usually the Department of Texas has the highest rates, but during the past year the Department of California had the highest relative prevalence The exposure of the troops during the railway riots of July and August, 1894, was undoubtedly the cause of this increased prevalence in the Department of California

Rheumatic Affections—The rate for these affections was somewhat less than during the previous year The cases were evenly distributed in the departments

Venereal Diseases—The admission rate for these diseases in the Army was 80 43 for the year causing a rate of 5 32 constantly sick per thousand of strength and occasioning 36 discharges and one death The admission rate is higher this year than it has been for a long time In 1893 it was 78 08, in 1892, 76 73, in 1891, 72 46, in 1890, 75.22, and the average annual rate for the decade ending with the last mentioned year was 79 09 Although the number of admissions was greater than usual during the past, the number discharged for disability was considerably less, 36 as compared with 53 53, 46 and 71 respectively in the four years immediately preceding These diseases were less frequent among the negroes than among the whites or Indians, the admission rates being respectively 47 46, 82 21 and 152 85 One seventh of the whole number of cases owed their origin to syphilitic infection and had an average duration per case of 40 17 days, one sixth to chancroidal infection with an average duration of 34 71 days, and over two-thirds to gonorrheal infection with an average duration of 20 70 days

Alcoholism—The prevalence of alcoholism in the Army continues to decline The admission rate for the past year was 30 94 per thousand of strength as compared with 33 97, 37 23, 40 01, 40 73 and 41 41 in the five preceding years and with 56 68 in the decade ending with 1889 Again, in 1890 no less than seventeen posts had more than 10 per cent of their average strength under medical care for drunkenness, in 1891, eleven posts, in 1892 ten in 1893, seven, and during the past year only four Captain W H Arthur reduced the statistics of alcoholism at Vancouver Barracks by dealing with drunkenness as with acute poisoning The stomach was emptied by the stomach pump and washed out with a warm 2 per cent soda solution after which the patient was given a bowl of hot beef extract with cayenne pepper He was then generally able, although perhaps unwilling, to go to duty

Consumption—Seventy-five men were admitted to sick report during the year for consumption, 44 were discharged and 17 died The admission rate per thousand of strength was 2 96 as compared with 2.85 in 1893, 4 34 in 1892 During the past three years consumption has been more prevalent in the Army than usual, on account of the susceptibility of the Indians to this disease

Injuries—The admission rate for injuries per thousand of strength was 244.21, with a total of 80 discharges (26 of which were for hernia) and 59 deaths The rates for the various races did not vary much from the average nor does that of the past year differ much from those of the preceding decade Ten homicides were reported—5 whites 3 negroes and 2 Indians, 18 suicides—15 whites, 1 negro and 2 Indians

The Influence of Age Arm of Service, Nativity and Length of Service on Liability to Disease—The report contains a series of tables based upon the statistics of the calendar years 1890–95, which show the relation of certain specified diseases and classes of disease to arms of service length of service, age, and country of birth of the soldiers comprising the Army The figures given in the tables are the average annual rates per thousand of strength for the period stated The change in the *personnel* of our small Army takes place so rapidly on account of the short term of service, discharges by purchase, desertion and other drains that the ratios may be regarded as the annual rates of an army of 135,338 men instead of the average annual rates of one of 27,067 for a period of five years These tables are therefore of greater value than those formerly published, although the absolute numbers under many of the headings are yet too small to give satisfactory ratios

Troops on Active Service—During the period of the railroad riots, July 3 to 18, 1894, 10 troops of cavalry, 4 batteries of artillery and 23 companies of infantry operated from a camp on Lake Front, Chicago, Ill A hospital of 20 beds was established The wards were floored and furnished with field cots, blankets and mosquito bars Outlying detachments serving without attached medical attendance were visited daily by a medical officer who held sick call and telegraphed to the field hospital for an ambulance in case it was found necessary to send in any of the sick for care and treatment

About the same time 2 companies of cavalry, 5 of artillery, 1 of infantry and 3 of the Marine Corps were concentrated at Sacramento, Cal The dining room of the railroad depot was converted into a hospital This command suffered much from malarial fevers in August

Classification of Diseases—Until recently, the classification of diseases and injuries used by the Surgeon General's office was based on that of the College of Physicians and Surgeons of England This system which was adopted a number of years ago is now inconsistent in many points with our present knowledge of the causation and processes of disease Such divisions and subdivisions as zymotic, miasmatic, enthetic, zoogenous, etc, belong to a past era in the progress of medical knowledge A new system of classification of the causes of disability has therefore been drawn up and has been used in the statistical tables presented with this report

Uniformity in Medico-Military Statistics—An International Commission of military medical officers met in Buda Pesth in September, 1894, under the chairmanship of Lieut Col J S Billings, Deputy Surgeon-General, U S A, and came to an agreement as to the character of the statistics to be published for comparative purposes by each of the countries participating in the convention A series of ten international statistical tables were issued for the consideration of the various military medical departments and for adoption if approved These tables have been examined by the Surgeon General and approved with certain modifications, the chief of which is the consolidation of the second with the third, and of the sixth with the seventh, as giving a better view of the facts represented The Commission suggested that the various departments begin publication with the statistics of the calendar year 1895, but as all the needful data were readily available, the Surgeon-General submits with his report the statistics of the past year in eight tables such as will satisfy the requirements of the Commission and permit of ready comparison with the medical statistics of other countries

Surgical Operations—The reports of operations performed show that medical officers are fully alive to the requirements of modern aseptic surgery, and even at isolated and frontier posts have, in the operations they have been called upon to perform, endeavored to carry out the principles of asepsis with the apparatus at hand Many interesting cases have been reported, particularly in the line of abdominal surgery Among them are ten cases of typhlitis or abdominal abscess, of which six recovered after operation, three died notwithstanding operative interference, and in one case the perityphlitic condition was not recognized during the life of the individual

Quarters—Most of the suggestions of medical officers during the past year have been directed to the prevention of over-crowding and the improvement of ventilation Crowding was noted specially at St Francis Barracks, Forts Sheridan and Sill, defective ventilation at Angel Island, Fort Robinson and Vancouver Barracks Over-crowding was reported in some of the guard houses, as at Madison Barracks and Forts Myer and Wingate At the first mentioned the guard room gives only 384 cubic feet to each of the guard and from 200 to 324 to each of the ordinary number of prisoners At the last, the air space per man in December, 1894, was only 217 feet

Drainage, Sewerage, Latrines etc—Faulty drainage is mentioned only at a few posts At Fort Barrancas the low ground in front of the post is covered with undergrowth, the ditches draining it having become more or less clogged

Past experience is cited as having shown that this has an important bearing on the prevalence of malarial diseases at the post and also upon mosquitoes which rise in swarms when the low ground is saturated The swamp in the northeast corner of the reservation at Washington Barracks is also noted, but it is represented as being more harmful to the adjacent citizens than to the troops The cellars in some of the quarters at Forts Niagara and Porter are occasionally flooded Since the occupation of the new post of Fort Brady, Mich the post surgeon has repeatedly called attention to the faulty drainage which permits the ashpits in the barracks to be flooded with water, particularly during the snow melting of spring The Locust Street sewer continues to discharge on the reservation at the Presidio of San Francisco, Cal

Water Supplies—Deficient supply was reported from four posts At Fort Assiniboine, Beaver Creek from which the supply is derived, became dry in August, 1894 Water for drinking and other domestic purposes was obtained from a spring in the neighborhood At Fort Hamilton and Columbus and Jefferson Barracks the deficient supply was remedied by improving the connections with the city mains from which each draws its water The question of water supply at Forts Reno and Clark remains unsolved At the former post the drinking supply is condensed from the ice machine or waggoned from Caddo Springs The results of an examination of the water from a boring in the river bottom in August, 1894 did not differ from those of analysis of well water made in May of that year The water was too hard for potable or domestic use At the latter post the Las Moras Spring was twice flooded by storm water in August, 1894 In May, 1895, the masonry approaches of the foot bridge below the springs were removed These had up to that time obstructed the channel of the creek in times of high water and favored the overflow of the springs by back water

At Fort Myer a temporary solution of the water problem has been effected by pumping water from the Potomac near the aqueduct bridge, a contaminated supply subsequently purified by the use of Columbia and Pasteur filters in the barracks and quarters The artesian well is understood to have been non-productive so far Suggestions of the prevalence of typhoid fever due to impure water supplies have been reported from Forts Leavenworth and Custer At the one post the unsedimented and unfiltered river water supplied by the Leavenworth city water works has often been condemned by medical officers The question of a pure water supply has been under consideration by the authorities of the military prison and some borings were made, the water from which was regarded on analysis as being suitable for use if freed from suspended earthy particles At Fort Custer the foul condition of the water supply is said to be due to the offal and drainage from the slaughter house of the Crow agency on the Little Bighorn River and from the use of the water for irrigating purposes before it reaches the post

Food—Very little adverse criticism on the food of the soldier or the methods of its preparation is found in the sanitary reports Usually these reports are to the effect that the food is ample in quantity, varied in kind and well cooked As issued by the Subsistence Department or provided for by contract the articles of the ration have been of good marketable quality

Clothing—The clothing issued gave general satisfaction Marked improvement was noted at northern posts in the issue of knit wool drawers and of a less irritating quality of undershirt, but these are said to be not yet what they ought to be The wool alone required to make suitable underwear can not be purchased for the price of that now issued

Habits, Cleanliness, Athletic Exercises, etc—A general appreciation of the habits of the men may be had better by a consideration of what has been said in discussing the prevalence of venereal diseases and alcoholism, than by extensive citations from the reports from individual posts The Post Exchange is not suggested as a causative agent in the brawls and breaches of discipline occasionally reported as the result of alcoholic excesses Usually these are attributed to the facility with which whisky can be procured in the neighboring civil settlements As a rule, the men are clean, well set up, and soldierly in appearance The facilities for bathing have been improved greatly of late years, so that current sanitary reports have no reference to the absence of means for this purpose, except at the recently established post of Key West Barracks, where there is only salt water bathing, and this, although valuable as an athletic exercise and recreation is unsatisfactory for the maintenance of personal cleanliness

ASSOCIATION NEWS

Department and Secretary of Public Health.

To the Members of the American Medical Association

The American Medical Association at its session in Washington in 1891, adopted unanimously a resolution favoring a Department and Secretary of Public Health—said Secretary to be a member of the Cabinet of the President of the United States, and appointed a committee to urge upon Congress the passage of a law for the creation of such a Department and Secretary This committee has been continued, with slight changes, up to this time, and have prepared and presented to Congress a suitable bill, and by such methods as were open to them have endeavored to secure its passage This bill is now pending in both Houses of Congress

In the meantime the Association has pledged itself anew at every annual meeting since 1891, and notably in the annual meeting in Baltimore last May, to continue the work necessary to secure the desired legislation Many State medical associations and many local medical societies have passed resolutions approving of the end in view, and these resolutions have, presumably, been sent to the Senators and Representatives of the respective States

As the result of these measures, considerable interest has been excited in Congress in favor of the pending bill, but not enough to secure its passage

Under these indicated circumstances it becomes our duty to make still further effort, and we appeal to members of the Association everywhere, to give us all the help they can It certainly seems to us that if the hundred thousand doctors in the United States would unite as one man and earnestly request of Congress the passage of the bill to create a Department and Secretary of Public Health, that the enterprise could not fail of success Surely, whatever a hundred thousand doctors would ask for would be granted

We therefore recommend

1 That every State medical association and every local medical society shall, as promptly as may be, pass resolutions favoring the adoption of our bill, and that such resolutions shall be published in the medical journals and copies forwarded to the members of Congress

2 That every doctor in the United States shall address a private letter in advocacy of our bill to the senators and representatives in Congress from their respective States Every citizen has the right to appeal to his representatives, no matter whether he is acquainted with them personally or not Can any one believe that if all the doctors in any State were to unite in soliciting the senators and representatives of said State to pass this bill, that such solicitation would not bear good fruit?

3 The medical journals of the country, as a rule, have heretofore given us generous assistance, and we heartily urge upon them a continuance of their efforts in our behalf

Veratrol, $C_8H_{10}O_2$, is described as a colorless oil, of an agreeable, aromatic odor, specific gravity, 1 086, boiling point, 205° C (401° F) It is made by acting upon veratric acid by baryta and heat It is soluble in alcohol, ether and oils From researches which have been carried out on synthetic veratrol, it appears that this drug possesses antiseptic properties in respect to certain pathogenic microbes—*Pharmaceutical Era*

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman Venetian Building Chicago, Ill , sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue Chicago

SATURDAY, NOVEMBER 2, 1895

THE DEFINITION OF EPILEPSY

The definition of a disease is generally supposed to give some adequate conception of its character, and any indefinite statement in this direction generally means that the ideas as to the disorder are vague, ill limited,or only partially understood Sometimes, however, a name carries a sufficiently clear though general idea, as in the term insanity while it would puzzle lawyers accustomed to every possible use of words to give a well rounded and complete definition With the term epilepsy, however, the case is not the same as with insanity , while it conveys to every one the general idea of convulsions or their equivalents, the definitions offered by high authorities clearly show that, as indicating a distinct disease, it is hardly employed with the accuracy and definiteness that should give the proper notion of a real morbid species One writer calls it "an affection of the nervous system characterized by attacks of unconsciousness," another speaks of it as "a disease in which there are convulsions of a certain type or sudden loss or impairment of consciousness," and still others mention various types according as they are "idiopathic," symptomatic, reflex or otherwise All or nearly all make loss of consciousness its chief characteristic in their definitions, but only to later make exceptions for the case of partial epilepsy in the subsequent descriptions In hardly any text-book is there a definition given that compactly and completely covers the ground as is done for most other nervous disorders, in all it is incomplete, requiring qualifications, and is often inaccurate

What is the propriety, for example, of calling epilepsy a functional neurosis, and distinguishing as a separate type all cases in which any gross organic disease can be recognized, when the connection of the convulsions with the latter is at best only assumed? A cerebral tumor localized in the brain, as a rule, no more demonstrates its exact relations with an epileptic attack than does an overloaded stomach or a diseased kidney , not, in fact, so much, since in these latter cases we can assume a toxic or disordered condition of the blood that may act directly upon the unstable nerve cells Nor is there any more propriety in separating Jacksonian from generalized epilepsy, as the lesions may be as obscure in one case as in the other The same may be said of infantile convulsions, which are only the reaction of an immature brain with undeveloped inhibitory powers to morbid irritations, or of the senile convulsive attacks due to the regressive changes of old age Epilepsy is simply and solely the symptom of cortical instability from whatever cause, and if it is ever exceptionally subcortical in its origin it must be due to the same irritability affecting the ganglionic representatives of the cortex in the basal portions of the brain The normal cortical cells, while a source, so to speak, of energy, are so balanced and controlled that these explosive morbid phenomena must be due to some actual physical disorder, whether this be from imperfections in development or from acquired defects through innutrition, intoxication, etc , as well as from gross disease With modern methods we are likely to learn more and more what these changes are, and the term idiopathic or simple epilepsy will be relegated to the general limbo for useless and forgotten names

The primary condition of instability once established, the epileptic attacks, varying according to the portion of the organ involved, from general convulsions to petit mal or the psychic equivalent, may be aroused often by a slight cause, whether it be reflex, toxic, emotional, or due to the irritation of gross disease, hence the distinction of these different forms of epilepsy is unjustifiable except as a mere matter of convenience in special cases The general definition of epilepsy that may be offered, therefore, is that it is a disorder consisting essentially in a condition of explosive cortical instability, and lack of inhibition, manifesting itself in general or local convulsive attacks, or in sudden temporary disturbances of consciousness and other psychic functions This includes not only the physical and intellectual manifestations, but also all emotional and volitional disturbances that may have to be classed under this head It does not unduly limit the disorder by making loss of consciousness its characteristic and it expresses the conception of what is coming to be universally recognized as the true pathology

With this conception of epilepsy in the mind, a clearer light is thrown upon the pathology and the treatment The futility of expecting to cure established epilepsy by simply cutting off sources of reflex irritation without attacking the primary condition is made self-evident, as is also that of attempting to find any single uniform lesion It is, as a clinical entity, a special form of disorder of cortical functioning, that may depend upon numerous and widely varying conditions

ACUTE PANCREATITIS AND DISSEMINATED FAT NECROSIS

One of the most interesting points in connection with instances of acute inflammatory affections of the pancreas is their frequent association with the condition which was first described by **Balser** (*Virch Archiv*, Bd 90, 1882) as disseminated fat necrosis The opinions that at present obtain, concerning the causes of these changes in the fat tissue are succinctly stated by **Thayer** in connection with the report of a successful operation for pancreatitis and parapancreatic abscess (*American Journal of Medical Sciences*, October, 1895) This case is really a very important one from a clinical standpoint, because it shows the possibility and importance of an early diagnosis and operation in acute pancreatitis It is the first case recorded in which the diagnosis has been followed by a successful operation Since the publication of the researches of **Fitz** on acute pancreatitis (Boston, 1889, also *Boston Med and Surg Journal*, 1889) in which he studied carefully his own cases as well as cases from the literature, a number of additional instances of acute pancreatitis have been described and some observations made that throw some light on the fat necrosis mentioned, as being frequently associated with acute inflammatory affections of the pancreas

Balser (loc cit) believed that these yellowish-white, opaque, small characteristic areas in fat tissue, that he termed disseminated fat necrosis were due to an overgrowth of fatty tissue, the central parts of the fat masses becoming necrotic from lack of nourishment, he believed the pancreatic changes to be secondary, because he found fat necrosis in bodies where no special symptoms had been present during life **Chiari** (*Prag med Woch*, 1893) regarded the process as degenerative, and could find no evidences of any fatty overgrowth **Fitz** (loc cit) thinks that there is a fat necrosis without any direct relation to severe lesions of the pancreas, and also that there is an inflammatory fat necrosis which is secondary to acute pancreatitis **Fitz** found in some of his cases, areas of round cell infiltration around the periphery of the necrotic foci and in some cases bacteria were also present **Langerhaus** (*Virch Archiv*, Bd 122, 1890) showed that the necrotic areas consist of a combination of lime salts with fatty acids and he advances the plausible suggestion that the process may take place as the result of the action of the fat splitting from the pancreas upon the fat tissue, the fatty acids afterward combining with lime Indeed, he states that he was able to produce similar changes in the subcutaneous fat of a dog by the injection of pancreatic extract **Rolleston** (*Trans Path Soc*, London, 1893) traced the cause of fat necrosis to disturbances of the trophic influences of the abdominal sympathetic system due to the extension of some morbid process from the pancreas

Balser (Vort Eleventh Congress f mat Med , 1892) made an additional communication concerning culture experiments, which were not finished, and the final outcome of which have not yet been published In 1891, **Welch** (*Medical News*, 1891) obtained the bacillus coli communis in pure culture from areas of fat necrosis, associated with acute pancreatitis, but he did not think that the necrosis resulted from a primary infection In a number of instances **Thayer** (loc cit) states that culture experiments by **Welch** have remained entirely without positive results

The real, exact cause, then, of these fat necroses is not entirely settled That the process may occur without pancreatic disease is beyond question, but in such cases the areas are usually limited to the interlobar fat tissue in the pancreas and such areas may be found, as every pathologist knows, in individuals in whom there have been no symptoms pointing to the process during life The areas can not be accounted for as due to direct infection, because cultures have proved sterile, both in instances without gross pancreatic disease, as well as in cases in which marked pancreatitis of undoubted infectious origin was present In view of these circumstances the observations of **Langerhaus** cited above become strikingly suggestive, areas, similar to those observed in connection with pancreatitis, may be produced by the direct action of pancreatic juice upon fatty tissue and consequently a primary lesion of the pancreas, of infectious or toxic origin, may allow the escape of the fat splitting ferment into the surrounding tissue which thus causes a secondary and sterile disseminated fat necrosis In connection with this, should be mentioned the experiments of **Hildebrand** (Trans German Society for Surgery, April, 1895, summarized in *Medicine*, September, 1895) who deligated the splenic part of the pancreas in cats and then tied all the pancreatic veins, in order to hinder the resorption of the collected secretion by way of the blood paths, and post-mortem he always found areas of fat necrosis in the pancreas itself, and in adjacent omentum and mesentery He obtained the same results by placing either pieces of pancreas, or the entire organ of one animal into the abdomen of another and, in one of these cases, extensive hemorrhage also occurred The areas of fat necroses were quite characteristic It will be seen that the results of **Hildebrand's** experiments appear to confirm the observations, as well as the suggestions of **Langerhaus** as regards the mode of formation of disseminated necrosis of fat

NEW YORK CITY HOSPITALS AND THEIR VISITING STAFFS

An important change in the manner of appointment of the visiting corps of surgeons and physicians at the county hospitals of New York County is predicted The hospitals which will be affected by the change are the Fordham, Harlem, Charity, and Gouverneur Hospitals, and all the institutions on Randall's, Blackwell's and Ward's Islands Bellevue Hospital is excluded

The Commissioners of Charities and Correction have decided to dismiss the medical boards in the hospitals under their control on November 1, and to appoint in the future only men recommended by the different medical colleges of the city The term medical board, as used in the city hospitals, means the staff of visiting and consulting physicians It is only in these posts that the changes will be made, the house staffs remaining as they have been No change at all will be made in Bellevue Hospital, as the medical board there has, since 1882, been composed only of men recommended by medical colleges It was the success of this practice at Bellevue that induced the Commissioners to make the change in other hospitals

CHICAGO MEDICAL INSPECTORS

The Civil Service Commission of the city of Chicago have postponed the examination which was advertised to take place November 7, until December 9

The Commissioners have decided that the examinations shall conform in general to those required for entrance into the Government Medical Services The following is the essential plan of examination, which will occupy about five days

1 The candidate will be required to pass a satisfactory physical examination, and in addition will certify that he labors under no physical disability

2 The candidate will then write a brief autobiography, and pass a short written examination in history, literature and physics He will then be examined in anatomy, physiology, chemistry (including bacteriology and toxicology), general medicine, general surgery, obstetrics, materia medica (including drug adulterations) and hygiene

3 The examination will conclude with a clinical examination at a hospital where exanthematous diseases are treated, and an accurate diagnosis of the cases will be required

From the foregoing it is evident that the Commission intend to raise the standard The salary of the Medical Inspector, it is understood, will for the present be fixed at $1,200 a year

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

This week we publish fifty-two pages of reading matter The vast pile of MS on hand in the office, admonished us once more that the space was too limited for the publication of the large amount of manuscript with which our friends have favored us After the conclusion of the current volume, it is in contemplation to make the enlargement a permanent one, as the great success of the publication seems now to fully warrant the additional expenditure We have not at any time thought it expedient to count the advertising pages, as making any part of the number of pages ! One of our esteemed contemporaries has the habit of counting its advertising pages in order to keep pace with the JOURNAL, but the practice is too transparent to make our readers at all envious, especially when they may easily look at the number of the last page of any even date and see for themselves that no weekly medical journal in America has given its readers more medical literature than their own

Not only has their JOURNAL given them a vast quantity of reading material, but at no time in the history of the ASSOCIATION has the quality of the articles been finer or of higher class, than it is to day The wisdom of the founders of the JOURNAL is more and more apparent every week

GOOD JOURNALS REPAY

DR ISRAEL B WASHBURN of Rensselaer, Indiana, writes to the *Medical Journal* of that State, his view of the comparative value of journals and formal treatises to the rural practitioner

"The country physician can use his money to much better advantage than in buying the larger treatises, by subscribing for as many good journals as he can read and, every three to five years, such works on special subjects as he needs There are few medical books that are not 'old and gray' in five years in these days of medical progress "

Sound advice We will add, subscribe only for journals of that high class that deserve to be preserved Bind the journal or journals that you find the most desirable for reference Unbound journals will seldom be consulted, and before long become a source of complaint to the housewife

CREDIT WHERE IT IS DUE

The obituary notice of SIR THOMAS LONGMORE which we published last week was extracted from the *British Medical Journal*, and by an inadvertence was not credited We are glad to say that, so far as we are aware, this is the first instance on record in which an article taken from another journal was not duly credited In our opinion there are few things more exasperating than to have articles copied from our JOURNAL without credit, or perhaps with that slipshod credit, "Ex" Some journals that are considered respectable, are hardened sinners in that regard

CORRESPONDENCE

A Domestic Test for Albuminous Urine

New York City, October, 1895

To the Editor —This is the title of a paper read by the writer at the last meeting of the New York Medical Association, held in New York City, Oct 15, 1895 Thinking that an abstract of the important part of that paper might be of some value to the readers of the Journal, it is sent to the Journal with the hope that you will deem it worthy of publication

The method of making this test is as follows pour into a test tube an inch of urine , with a dropper, drop carefully upon the surface of the urine half its quantity of alcohol If albumin be present in the urine, a white line will form between the two fluids, the same as in the cold nitric acid test

The other method is to put the alcohol in the test tube first, and drop as before, the urine into it If albumin be present in the urine, it will be made known by a white wave of coagulated albumin following the urine as it sinks to the bottom of the test tube The urine being heavier than the alcohol will gravitate to the bottom of the tube very quickly After a small quantity of urine has been added, the alcohol will become opaque with the coagulated albumin This test is so sensitive that the one hundredth of 1 per cent of albumin when present in the urine can be detected

The writer has used this method for about a year, both in private practice and hospital work It has been found to be the most convenient and most delicate of tests

Mucus will be coagulated if it be present, and may be mistaken for albumin Filtering before testing will eliminate mucus, if one is still in doubt, any of the control tests for mucus can be made No other ingredient of abnormal urine will give any trouble, more than when any other method for testing urine is employed Alcohol, if of the strength of 60 per cent , when clear, will answer every purpose, excepting one of delicacy

A glass tumbler may be used when it is impossible to obtain a test tube No heat, no acids required So convenient is the test that the physician can not be excused if he fails to discover the presence of albumin

The writer is convinced by a year's experience in the use of this method that if the profession will give it a trial none will be disappointed Any doubts which may remain in one's mind, can be removed by control tests Few of us rely upon one single test, by whatever method made

School Books on Physiology and Hygiene

Hartford, Conn , October, 1895

To the Editor —We inclose the following report, which at this time has considerable medical interest in many sections of the country During the past few years laws have been passed in Congress, and the Legislatures of forty-one different States, requiring instruction in the public school on physiology, hygiene and the effects of spirits and narcotics on the human body A large number of school books have been prepared to meet this requirement, nearly all of which have been compiled and edited by medical men, many of whom are eminent in the profession

Many of these works have been assailed in the daily press and denounced as containing errors, but the criticism so far has been limited to mere statements The authors of these works have invited from the medical profession the most critical examination and inquiry concerning the accuracy of the facts stated

This report is in accordance with this request, and the object (in which all medical men are interested) is to eliminate all possible errors and raise the character and accuracy of such works to the highest possible standard

Very truly yours, H A B

REPORT

We, the undersigned physicians, have been requested to examine and report on the various school physiologies which have been introduced to comply with the laws requiring temperance instruction in common schools

Our special attention has been directed to that part relating to the effects of alcohol, opium and other narcotics on the human body We have received and carefully examined eight different series of books called by the following names "The Pathfinder," "Appleton's," "Eclectic " "Union," Blaisdell," "Dulanie's," "The Health Series," and "Martin's High School Physiology "

As a result of this examination we are unanimous in opinion that the statements and teachings of these works concerning the effects of alcohol and other narcotics on the body are correct, and fully supported by the most authoritative studies of scientific investigators up to the present time

We are also of opinion that in both letter and spirit, these works are highly commendable, particularly in the admirable groupings of physiologic and hygienic facts, with excellent illustrations and clear concise statements

The practical character of these books commend them to us, and the interest and value of their teachings would seem to place them among the most important subjects that can be used in our public schools (Signed)

West Tennessee Medical and Surgical Association

Paris, Tenn , Oct 23, 1895

To the Editor —Please announce the meeting of West Tennessee Medical and Surgical Association at Covington, Tenn , Nov 21 and 22, 1895 Very truly yours,

I A McSwain, M D , Secretary

SOCIETY NEWS

"American Medicine "

In response to a toast at the annual dinner of the Chicago Gynecological Society, Oct 18, 1895, Dr John H Hollister, said

Let no man be over-anxious about his reputation If he intend the right and does his best ultimately that reputation will take care of itself and of him too This is true of nations individuals—true of nations Great as has been the progress of nations during the last 300 years, the development of America in that period has been the phenomenal fact Cradled without parental care, it came to its estate without the help of other nations , in fact, it grew by reason of their neglect A noble *manhood* was its only inheritance All else is of its own creation For nearly two centuries we were esteemed a semi-barbarous people by the crowned heads and the *elite* of Europe, and their prejudices have only been in any measure conquered by our sublime indifference

The struggle to make for ourselves a name and a place among the foremost, has been indeed severe, but the issue is no longer doubtful You who have met this prejudice on foreign shores know well how strong it yet remains, but you know full well that, as professional men, you have nothing left to fear, and that especially in medicine and surgery Americans have no apologies to make We are to be courteous *ever*, but deferential or craven, if ever we were, *nevermore*

Happily for us, American history holds no relationship with the mythical ages Our genesis was clearly written and the successive stages of our development are sharply defined From the landing of Columbus to this hour, ours has been a story of thrilling interest, and I am asked within these ten minutes to outline to you the agency of medical men in the accomplishment of present results Were every page of mine a volume, the half of their records in the making of American history could not be told Indulge me, therefore, in a little free-hand drawing while, from a single standpoint, I seek to sketch in briefest outline the deeds of those who tower in the distance like magnetic peaks, and others hardly less conspicuous, who coming a century later command a place in the immediate foreground

For the first hundred years and more, in our colonial history, our noted physicians were educated abroad—in Edinburgh and London and Paris Of medical schools we had none, and yet, despite this, and in the absence of foreign culture, there grew up in these western wilds a host of doctors whose successes in the treatment of diseases in those colonial days is still a matter commanding our respect But another day dawns It is the eve of the Revolution! Our first scene is laid in Boston, the time June, 1775 The whole country is aflame, for a crisis is at hand

If now there be one more conspicuous than his fellows (unless it be Samuel Adams) that man is a physician—a student of the eminent Dr Lloyd He is called from his profession, for Boston is in peril He is made president of its Committee of Public Safety, soon he is a major-general, but, seizing a musket, he is foremost in the fight and falls, as a private would fall, in the battle of Bunker Hill His name is Joseph Warren

In the annals of our medical history the name of his brother John is even more conspicuous He was senior surgeon in the improvising of Cambridge hospital in 1775, and cared for the wounded of Bunker Hill He was the founder of the medical department of Harvard College in 1783 His standing as a civilian may be inferred from the fact that he was the first to pronounce a Fourth of July oration in the famous patriotic city of Boston He was continuously the President of the Massachusetts Medical Society from 1804 to the date of his death in 1815 Following in his illustrious footsteps came another notable, his son, John Collins Warren He took his father's chair of surgery in Harvard in 1815, and held it in active service for sixty-two years In 1820 he united with others in the founding of the Massachusetts General Hospital In 1828 he founded the *Boston Medical and Surgical Journal* He introduced ether into surgical practice in 1846 He died in 1856, bequeathing his body to his school and his skeleton to his museum

It seems a cruel thing to leave so much of other early eminent physicians of Boston unsaid But the scene changes We come now to Philadelphia The time is also 1776 Benjamin Rush has studied in London, in Edinburgh, in Paris He stands in the forefront of his profession, and a most accomplished citizen as well Here too, in Philadelphia, the question of revolution is at fever heat A provisional council of the State is called He is there as a member In that body it is he who introduced a resolution "to consider the expediency of a Declaration of Independence" He was a member of the Continental Congress in June following He signed that Declaration as formulated by Jefferson, when men were to hang separately if they did not hang together He was both medical and surgeon general of the central division of the American armies in that most critical period In 1785 he founded the first dispensary in the United States Such were his invaluable services during that terrible invasion of yellow fever in 1793 that from most of the crowned heads of Europe, as well as from his own countrymen, he commanded most flattering testimonials Sparse as was our population in that early day, he gave instruction to over two thousand medical students, and despite its unpopularity was president of an abolition society beside

Nor must I, in the moments that remain, forego the name of Nathaniel Chapman Stung by the question of the *Edinburgh Review*, "In the four quarters of the globe who reads an American book, or goes to an American play, or looks at an American picture or statue? What does the world yet owe to American physicians and surgeons?" he determined that America should be heard from , and in 1820 he founded and edited the *Philadelphia Journal of Medical and Physical Sciences*, the first American medical journal, which seven years later became our well-known *American Journal of Medical Sciences* A monument to his memory is one of the fitting things yet to be, and if finally, it shall be an accomplished fact within his lifetime, Gihon will be happy

With the opening of the present century, especially after the war of 1812, with the return of prosperity to our people began the marvelous development of education, and prominent among educators were those devoted to the teaching of medicine and surgery From 1830 to the present date we founded over one hundred medical colleges We can not better measure the progress of medicine in America in the last half century than by comparing the colleges of 1850 with those of 1895

But, gentlemen, be it remembered that this wondrous evolution is not a matter of accident But for those earlier colleges, the best that could then be, our present grand universities would not now have being As I recount the planting of these medical colleges which were nearly all founded within my remembrance, the unselfish and unpaid labors of a host of men are recalled to mind—men who builded wisely in their day , men into whose labors you have entered—you hardly know at what cost Time would fail to tell you of these men even by name—of those just passed from our presence and of those who still linger among us, full of years and of honors—by whom a great preparatory work was so well achieved The Warrens, the Storrs and the Bigelows of Boston , the names of Valentine Mott, of Gurdon Buck, of Willard Parker, Alonzo Clark, the elder Flint, Peasley and Nathan Smith of New York , Chapman, Jackson, Dewees, Meigs, Dunglison, Horner and Gross of Philadelphia , Massey, Drake and Dawson of Cincinnati , Miller, Gibson and the Yandells of Louisville , Storrs and Jones, Bemiss and Richardson of New Orleans , Eve, Briggs and their confrères of Nashville , of Pope and McDowell and J B Johnson and Hodgen of St Louis , of Brainerd and Herrick Blaney and Freer, Johnson, Allen, Byford and Gunn, Ross, Jewell, Jackson and Parks, who have ceased from their work , and of Davis and Andrews and Isham and Bartlett of Chicago who still remain—*these all*—and their *associates* whom time does not permit me to name, have wrought with a success which you yourselves best know, for the development of American medical institutions and American medical literature

From this list, I purposely omit the names of McDowell, Symmes, Atlee and Battey, and a list of living eminent gynecologists, knowing that from yourselves at such a meeting as this, they will doubtless receive tributes more ample and more just—and I close with this single suggestion your predecessors were by no means satisfied with their then present labors, but they prophesied your coming They foresaw your greatly improved environments, your laboratories, your aseptic hospitals, your possibilities for achieving results which with them were impossible They have left those prophecies on record, and in memory of those who are dead, we, who still live, look earnestly, hopefully and confidently to *you* for their fulfillment

PUBLIC HEALTH

Camp Jenner, Eagle Pass, Texas—Passed Assistant Surgeon George M Magruder reports to the Surgeon-General of the Marine-Hospital Service under date of Oct 21, 1895, (Abstract of Sanitary Reports) that the camp was closed on that date and all refugees discharged

Contributions to the Study of Trichinosis—While the classical investigations of Leuckart, Zenke and Virchow have cleared up many points concerning the nature and pathogenesis of trichinosis, our knowledge is yet somewhat unsatisfactory as regards the route by means of which the trichinæ reach the muscles from the intestinal tract Leuckart believed from theoretic considerations that the embryos reach the muscles by means of independent locomotion along the connective tissue bands, but this conclusion was not based on experimental investigation In order to decide this question, Askanazy (*Archiv fur Pathologische Anatomie und Physiologie und fur Klinische Medicin* Bd CXLI, Heft 1, S 42) made use of animal experiments He examined rabbits dead from artificial trichinosis, as well as pieces of the tissues which were removed from the intestines of rabbits, for instance, under narcosis In this way he was able to study thoroughly the route selected by the trichina and he made the interesting observation that almost without exception only the female animals undertake emigration into the organism, a fact that corresponds well with the clinical conditions, namely that the feces contain male trichinæ in much greater numbers than females The process was found to be as follows the female intestinal trichinæ become closely adherent to the intestinal mucous membrane, often encircling the villi in a spiral manner and then they pass in an active boring manner into the wall until they reach the central chyle vessels which are penetrated The birth of embryo trichinæ now occurs, and only a small part of the brood is discharged in the lumen of the intestines, the majority of the young animals pass directly into the chyle vessels From the lymphatics they reach, first, the mesenteric lymph glands and, passing this filter, they are emptied through the thoracic duct into the general circulation It is, nevertheless, a very striking fact, that the young worms localize in the muscular tissue and, especially, that they seem to prefer certain definite and well-known muscle groups Askanazy attempts to explain this circumstance by resorting to chemotaxis as the most rational mode of explanation He succeeded in finding young trichinæ in small hemorrhagic lung foci where they had become arrested in the form of minute emboli The route by which the embryo trichinæ reach the muscles is consequently not the connective tissue strands but the lymph- and the blood-vascular system Askanazy also attempted to solve the problem of whether or not the survival of one infection resulted in any degree of immunity to succeeding infections, but his experiments as far as they went failed to show any immunity In one case reinfection occurred in a rabbit that had survived the first infection for half a year Several plates of colored illustrations make quite plain the observations outlined above

Medical Climatology of Mexico—The area of the vast territory of Mexico is 740,970 square miles, with a population of 11,632,924 souls The country may be divided into three regions 1, the coasts of the Gulf and the Pacific, up to 1,000 meters in height, a sandy porous soil or a sedimentary, wet, clayey soil covered with earth and very conducive to vegetation 2, between 1,000 and 2,000 meters the large and small alluvial valleys, cultivable, some conducive to the formation of marshes, others are chalky with stunted vegetation 3, from 2,000 to 3,000 meters, a small section of the rest of the country, with its mountains The Mexican coasts occupy a considerable extent Those of the Gulf measure 2,300 kilometers in length They are very low, sandy and marshy, those of the Pacific have an extent of 9,000 kilometers From the preceding topographic and orographic conditions it is seen that about two-thirds of Mexico lies in the temperate zone, the rest in the torrid The low lying regions are extremely insalubrious Palustral fevers are endemic, as is typhoid fever These conditions are explained by the luxuriant vegetation, the tropical temperature and the excessive humidity Among the endemic diseases of Mexico beside paludism (*cocoli rtli*), are helminthiasis, yellow fever, climatic fever, tetanus, pellagra, *vomito prieto* According to Dr Ruiz, paludism is to be found in the region of Vera Cruz which is covered with a tropical vegetation and has a damp warm atmosphere, as well as in the mountainous fertile region of Sonora The only localities exempt are those having a rocky soil, good water and a low mean temperature Yellow fever is observed on the coasts, especially from April to October The climatic fever presents itself under different aspects according to Guyon, as bilious, inflammatory, and typhic, "but in all its phases it has a special characteristic which makes it a nosologic entity, that is, the disease is not localized in the liver nor in any other viscus, and it is not induced by the palustral agent" Syphilis is found in all social classes, and is so diffused that its victims are to be found in hamlets as well as in cities "Mexico, the capital of the Republic," writes a distinguished hygienist, "is gaily constructed in a vast unhygienic area of the great Mexican valley" The population in 1890 was estimated at 451,246 The federal district which comprises the capital has an area of 463 square miles The extreme temperatures are, maximum (in the shade), 31 60 degrees C, minimum, 1 07 below zero, mean, 15 50 The general mortality rate is 40 per 1,000, and in nearly all localities of the federal district, it is even higher The prevalence of infectious disease in this district is very marked Of late the Superior Committee of Hygiene has advised the construction of a sewerage system, and the maintenance of pure drinking water, in order that, as Dr Samuel Gache remarks, the mean duration of life, which now is but twenty five years, may attain a higher figure, the resources of the country be increased and sanitary science have gained a new triumph[1]

Cholera in Honolulu—The sanitary column of the New York *Independent* for October 10 quotes from a recent Honolulu paper some suggestive statements regarding the spread of cholera at the place named The fountain head of the disease was among the Chinese on the SS *Belgic* where it was limited and stamped out, but extension to the native population was not prevented The exact method of this extension has not been satisfactorily explained, but the following has been offered as showing certain of the unusual environments of that community, as well as certain of the life endangering habits of the native population

"Mrs Emma M Nakauina, an intelligent and able half-white lady, and one of the highest authorities on such topics, has written an article for the *Pacific Commercial Advertiser* of September 5 that seems to afford a satisfactory clue She takes as a starting point the fact that the Chinamen who died at quarantine, died of undoubted cholera The practice has been to bury quarantined persons, without coffins, on a sandspit very near to the home of certain women who make a business of gathering and selling in the fish market crabs, limu and mud fishes Among these crabs are two varieties that are described and named with a word that means 'corpse eating,' from their well-known fondness for animal matter, especially decaying human flesh, and these crabs have been met at night half a mile inland from the sea, seeking decomposing animal matter, and the natives bury their dead far inland to preserve them from the ghoulish raids of these creatures At the very beginning of the epidemic a festivity known as a *luau* feast was held in Iwilei—a portion of Honolulu—and Mrs Nakauina, from her knowledge of the habits of her race, makes no doubt that the crabs and limu caught in the immediate vicinity of the quarantine graveyard formed part of the feast, and she says, very positively 'Now, those crabs at the previous high tide, perhaps an hour before, had themselves been feasting on the bodies of those cholera patients, buried on the sandspit immediately to the seaward of the residence of these fisherwomen Here was direct, undiluted contagion' And it should be understood that the crabs, after an interesting method of preparation, are eaten uncooked The lady elaborately describes the method of the natives in using the crabs, and leaves little doubt on the mind as to the complete deadly career of the microbes Moreover, she shows that the conduct of the Kanakas, owing to ignorance, is exactly parallel to that of the southern negroes, who could not be compelled to destroy yellow fever infected garments by burning, but would hide them, and the natives of Hawaii wash blankets and bedding in the running streams, unwilling to burn them, and skeptical of the danger That the dark places of the earth are still 'habitations of cruelty,' is shown afresh by a horribly revolting superstition still holding sway over the minds of many natives If a person has an enemy, he hires a *kahuna*, or witch, to 'pray the enemy to death'—a process called ana anaing said enemy—no mention being made of any surreptitious aid the witch may have given to his prayers If the ana-ana is effectual, the relatives of the dead person have their innings by taking some of the hair and nails, or, preferably, some of the excreta of the dead person, wrapping it in a clean new bit of cocoanut fiber cloth, and placing it under a stone in some water source, in the firm belief that the essence of the dead will spread out in the water, and if drunk by the person who was guilty of ana anaing the departed, would cause his death in a short time With our knowledge of the diffusion of bacteria, we shudder at a proceeding matched only by a tie on the railroad or a dynamite bomb The ignorant islanders did not lay the early deaths to the cholera-infected crabs, but they had all partaken of a pig that had been bought with the proceeds of a horse that had been stolen, the owner of the horse had employed one of the most powerful (unscrupulous?) of the witches to ana-ana the theft of the horse, hence the deaths, in their eyes It is no wonder that the intelligent lady who fathomed the cause of infection urges the Health Board to guard springs and water courses"

Health Reports—The following health reports have been received by the Supervising Surgeon-General, Marine-Hospital Service

SMALLPOX—UNITED STATES

New Orleans October 12 to 19, 5 cases, 1 death
New York City October 19 to 26, 1 death
Detroit, Mich October 12 to 19, smallpox reported
Rochester, Mich October 18, 1 case
Arizona, Nogales October 24, 2 cases
Arkansas, Clay County September 18 to October 22, 3 cases, 7 deaths

---

[1] *Journal d'Hygiene*, 1895, No 984

SMALLPOX—FOREIGN

Bologna October 5 to 12 1 case
Dublin October 5 to 12 24 cases, 1 death
Gibraltar September 30 to October 6, 1 case
Glasgow September 29 to October 12, 2 cases
London, Eng October 5 to 12, 158 cases, 2 deaths
Madrid October 1 to 8, 8 deaths
Montevideo September 14 to 21, 5 cases
Naples October 5 to 12, 7 cases, 7 deaths
Paris October 5 to 12, 1 death
Prague September 29 to October 12, 2 cases
St Petersburg September 29 to October 5, 8 cases, 8 deaths
Tuypan October 5 to 12, 5 deaths
Warsaw September 29 to October 12, 2 deaths
Singapore August 1 to 31, 1 death
Constantinople July 1 to 31, 41 deaths

CHOLERA

Bombay September 17 to 24 1 death
Roubaix September 1 to 30, 38 deaths

YELLOW FEVER

San Juan, Porto Rico September 21 to 28, 6 cases, 5 deaths September 28 to October 5, 5 cases, 1 death

SELECTIONS

Shortening of the Femur—Mr Thomas Bryant has contributed to the *Press and Circular* a recital of his experience in regard to shortening of the lower limb, especially in those cases where the femur is liable to be inculpated He says that in those cases of shortening of the lower extremity it is essential to closely investigate the condition of the neck of the femur If this plan be followed, as a regular rule, the explanation of many cases of shortening otherwise obscure and baffling, will be rendered plain The causes of shortening of the femur may be grouped into five varieties, namely

1 Impacted fracture of the neck of the femur

2 Arrest of growth of the neck, following disease the result of injury

3 Disease of the hip joint

4 Arrest of growth of the lower end of the femur from disease of the epiphysis

5 Arrest of growth of the lower end of the femur following disorganization of the knee joint

When the shortening of a leg amounts to a quarter of an inch and no more, the defect may be disregarded, this is not unfrequently present naturally or congenitally Again, half an inch shortening is by no means infrequent after fracture of the thigh In measuring for any shortening that may be present in a lower limb it is a good plan first to compare the length of both limbs from the top of the great trochanter of the external malleolus If the measurement be the same on both sides, then it is obvious that the shortening must be confined to the neck of the shorter femur, excepting always those possible exceptional cases, just above referred to, wherein there is the normal or non accidental disparity

Pyemia due to a Capsule Bacillus—Chiari (*Prager med Wochenschrift*, 1895, No 24–27) described a case of pyemia following an ascending suppurative nephritis in which the bacteriologic examination demonstrated the presence of a capsule bacillus as the etiologic agent The post-mortem examination showed in addition to certain old changes, suppurative nephritis, suppurative prostatitis and cysto pyelitis, acute endocarditis, and finally an otitis media and a meningitis In all these foci was found a bacillus which showed a distinct capsule This bacillus was pathogenic for all ordinary animals used for experimental purposes Rabbits were most resistant Subcutaneous injection produced suppuration, intravenous injection caused a rapidly fatal septicemia, injection into the kidneys caused suppurative nephritis with consecutive septicemia In guinea pigs the intra-abdominal injection caused diffuse peritonitis and death in twelve hours Mice died very soon after subcutaneous injection at the root of the tail This bacillus did not lose any of its virulence after repeated cultivations It was not stained with Gram's method, it grew rapidly in high glycerin-sugar-agar, producing abundant gas It was distinguished from the Friedlander's pneumonia bacillus by certain cultural peculiarities, by being markedly pathogenic for rabbits and by being fatal to mice after subcutaneous injection Sections from the diseased organs showed that it had a close relation to the morbid processes and that its presence could not be referred to post-mortem invasion In all likelihood, the point of entrance was the urethra, hence the cystitis, the prostatitis and the ascending nephritis From the suppurating foci in the kidneys, the bacilli invaded the blood and caused the endocarditis, the meningitis and the otitis

Pathologic Relations of the Liver and Intestines—Professor Hanot of Paris, in concluding his brilliant address on "The Intestines and Liver in Pathology," before the Congress of Internal Medicine recently held in Bordeaux, summed up as follows[1] Physiologically there exist intimate nervous and circulatory relations between the liver and intestines The liver is one of the essential parts of general nutrition, it feeds all organic activity and protects it against poisons, and, lastly, it creates the bile Thus the liver maintains the nutritive equilibrium of the intestine, it continually neutralizes the poisons which arrive at or are formed in the latter viscus, it also aids in the special work of digestion The physiologic services rendered by the intestine to the liver are not so marked It brings to the liver a part of the elements of its nutrition and of its special energy, it assists the liver in its digestive function and perhaps assists also in its anti-toxic action The intestine appears to be a vestibule for all the toxic and infectious agents going to the liver in combinations and in multiple proportions—alimentary poisons like alcohol, digestive poisons like acetic, lactic and butyric acids, microbes and their toxins Modern science has corrected an error of the old pathology—the portal vein is not the sole carrier of poisons, it brings only external poisons so to speak, the hepatic artery in its turn brings those from the interior of the organism Again, if the portal vein brings infection from the intestine to the liver, the hepatic artery distributes it generally The noxious influence of the intestine on the liver is only exercised when the latter organ permits it, it is entirely subordinated to the hepatic condition It is the state of the relations between the liver and the intestine from a pathologic point of view which is the beginning of the doctrine of intestinal antisepsis We can now readily conceive that intestinal antisepsis ought not only to comprehend the action exerted directly on the intestine, but also the indirect action exerted on the liver While we are neutralizing the poisons in the intestine we must maintain or assist the antitoxic power of the liver which helps to annihilate them In destroying part of the poisons in the intestine we preserve the liver so to speak Again, by maintaining the antitoxic properties of the liver we defend it against the products of intoxication reaching it from the depths of the tissues and which are added to the poisons of intestinal origin In short antiseptic measures are efficacious only when hepato-intestinal antisepsis is maintained

The Physician in Plato's Republic—The *Lancet* has the following scholarly note that reveals the mind of the great Greek philosopher concerning the status of medicine in his own time To those of the profession who are interested in historic reflections, it will be pleasing to note that Plato gave precedence to the physician, empirical though he was in that age, over the contemporary theologian or "hierophant" In Plato's scheme the classes that embrace the artist, the ruler and the merchant were those who stood superior to the physician The physician stood fourth in a series of eight classes The *Lancet* says "In a curious passage in one of the most famous of his dialogues—the Phædrus—Plato sketches his view of the doctrine of the transmigration of souls The soul which has seen most of truth in its former state comes to the birth as a philosopher or artist, or musician, or lover, that which has seen truth in the second degree shall be a righteous king, or warrior or lord, the soul which is of the third class shall be a politician, or economist, or trader, the fourth shall be a lover of gymnastic toils or a physician, the fifth a prophet or hierophant, to the sixth a poet or imitator will be appropriate, to the seventh the life of an artisan or husbandman, to the eighth that of a sophist or demagogue, to the ninth a tyrant 'All these,' says the philosopher, 'are states of probation, in which he who lives righteously improves, and he who lives unrighteously deteriorates his lot' The order of precedence in the above list is very curious and highly characteristic of the Hellenic mind The philosopher at the top of the scale and the tyrant at the bottom show that even Plato was not free from the prejudices of his nation and his caste The place he assigns to the physician—viz, fourth in the scale—is not a very elevated one, and it is somewhat singular to find him bracketed with the lover of gymnastic toils It is something, however, to find that the 'prophet or hierophant'—the ancient representative of an important profession—is placed even lower—viz, fifth Plato's comparatively low esteem for the profession of medicine is not difficult to understand, *since at a time when anatomy consisted of a few crude facts and physiology did not exist* it was impossible that medicine could command the reverence of any profound and penetrating intellect We find Plato constantly in his dialogues alluding to medicine as if it consisted of little else but giving a purge or an emetic No doubt Hippocrates was a man of profound genius and of immense knowledge, considering his time, but it is very unlikely that the average practitioner rose above the level of the mere drug giving empiric Lovers of Plato, who, we trust, are not few in the profession, may read their favorite author without feeling aggrieved that in his appreciation of medicine he did not rise above the level of his time It is probable that the average practitioner of those days combined much presumption and not a little chicanery with a plentiful lack of real medical knowledge, and it can hardly be a matter of wonder that the philosopher looked askance upon such pretenders"

[1] Le Bulletin Medical Aug 18 1895

Inguinal Hernia of the Gravid Uterus—Rosanhaff in the *Semaine Medicale*, Oct 2, 1895, from *Archives für Klinische Chirurgie*, vol XLIX, Bd 4, reports a remarkable case of inguinal hernia of the gravid uterus with premature delivery, and finally an operation for the radical cure of the hernia with recovery of the patient The patient was a woman 45 years of age, who entered the surgical clinic at Moscow for left inguinal hernia, which she had noticed for about five years In February, 1893, the hernia had become irreducible, and the preceding June was taken with rapid growth coincident with cessation of the menses The patient had had twelve children and had been delivered of the last three, notwithstanding the existence of the hernia On her arrival in the clinic in January, 1894, she presented in the left groin a tumor which descended within 6 centimeters of the knee and had the appearance of a very large inguinal hernia Its form was ovoid, and it measured 45 centimeters from above downward, while its diameter attained 80 centimeters at the largest place The integuments which covered it were very thin and deeply pigmented The tumor was dull but movable and presented a compact mass in its interior It was dull on percussion and a *bruit* could not be heard on auscultation The patient had never perceived any fetal movement The neck of the uterus was very much raised and to the touch was in continuity to the hernial tumor On Jan 25, 1894, the patient lost a great quantity of amniotic liquid and the tumor considerably diminished He was able to recognize the position of the fetus, and its head was found in the dependent portion of the sac corresponding to the neck The neck was turned to the left side Two hours after the flow of waters there began contractions of the uterus which were minutely observed, and they consisted of peristaltic movements from the fundus of the uterus and were very rapidly propagated from above downward, but the uterus in its entirety contracted energetically, and its transverse diameter was diminished at the same time that its antero posterior diameter was elongated The contractions of the uterus were not accompanied by any painful sensation, they terminated alone and without participation of the abdominal muscles, and a fetus of the weight of 2,200 grams was expelled The next day the womb and a portion
of its adnexa were easily reduced into the abdominal cavity
The hernial ring was so large as to easily admit the hand
the left ovary and a part of the tube of the left side resisted
taxis The symptoms following the accouchment were ab
solutely normal, but unfortunately knuckles of intestine at
tached themselves to the hernial sac and escaped into th
place left free by the uterus On April 7 it was decided t
practice an operation for the radical cure of the hernia Af
ter resection of the ovary and the left tube, which were irre
ducible, and the reduction of the intestinal folds, he resecte
the vast sac and closed its neck by sutures He then mad
an occlusion of the ring and terminated the operation b
suturing the wound after having excised the integument
that were in excess The patient left the hospital cured
about a month and up to the date of the report had not ha
any return This case, says the reporter in the *Semaine Med*
icale, is unique of its kind, for on one part the accouchmen
is operated by the uterine muscles alone, and for anothe
part the uterus was able to be reduced into the abdomin
cavity, while all the other cases of uterine hernia heretofor
reported have been irreducible The author believes th
the hernia and the left tube, as well as the intestinal fol
originally formed the contents of the sac in which the uter
penetrated more slowly

Electrotherapy as a Means of Diagnosis in Gynecology—*Dr*
Apostoli, (British Medical Association, 1895) after a lo
and thorough trial of his method, has come to the followi
general conclusions

1 The faradic current of tension (generated by the c
of long and fine wire) applied to the uterine cavity, accor
ing to the rules established by Dr Apostoli in 1883, reliev
for a longer or shorter time, all ovarian pain of nervous
hysterical origin, but remains powerless or nearly so
cases of ovarian pain caused by inflammatory lesion of t
peri-uterine tissue or of the appendages

2 The same faradic current is therefore useful in diag
sis, inasmuch as it helps us to distinguish the nature of
called ovarian pain, and to determine rapidly the different
diagnosis between hysterical and inflammatory ovarian pa
Where the two kinds of pain exist in the same patient,
are helped to understand their nature by the fact that
one is relieved and the other is not

3 If, then, the curative effect of the faradic current cle
up or rectifies a doubtful diagnosis, it protects us at
same time from undertaking a useless operation On
other hand, if the same faradic current proves ineffect
the lesion being inflammatory, we are led to resort to a s
plementary galvanic treatment or to a surgical operat
sooner or later

4 The constant galvanic current, applied to the uter
cavity in doses gradually increasing from 50 to 120 milli
pères, according to the rules published by Dr Apostoli
1884, and bearing in mind the individual susceptibility
tolerance, will be almost always supported without m
pain during the séance, and without febrile reaction af
ward, if the parts adjacent to the uterus are free f
inflammation

Simple cystic, peri uterine tumors, which are nei
inflamed nor suppurating (such as ovarian cysts and hy
salpinx), may also show perfect tolerance of the galv
current

The galvanic current is also sometimes perfectly
ported by cases in which the uterus is surrounded by
inflammatory products or exudations no longer pathog
5 There are three classes of cases which should be
sidered as exceptions to the preceding rule, for they
the galvanic current more or less badly, though they do
necessarily produce much febrile reaction after the séa

They are (*a*), certain forms of hysteria, (*b*), fibro c
tumors of the uterus, (*c*), enteritis with false membr
It is generally easy to diagnose these cases of intolera

6 All acute peri-uterine inflammation (of the pelvic
ular tissues, of the peritoneum and especially of the ap
dages) will cause the galvanic current to be badly b
when it passes 40 or 50 milliampères, and will cause int
able pain and febrile reaction when carried beyond
intensity

7 The intolerance for the galvanic current is gene
proportionate to the extent and gravity of the lesion
ferred to, and increases with the intensity of the cu
employed—especially when it passes 40 or 50 milliamp

8 All inflammation of the appendages which is
ble (symptomatically at least) without radical opera
will bear the galvanic current better and better, and

will be a corresponding improvement of the prominent symptoms such as pain and hemorrhages The intolerance noted at the beginning progressively disappears

9 All grave inflammatory lesions of the appendages, and notably all suppurative processes which are incurable (even symptomatically) by conservative means, show the same intolerance from the beginning to the end of the treatment which was noticed at first, and which is apt to increase instead of diminish if the treatment is continued

10 Thus the simple study of the tolerance or intolerance of the intra-uterine galvanic treatment, and especially of the post operative pain and fever occurring on the evening of, or the day following the treatment, enables us to make the diagnosis It also in four or five séances, given twice weekly informs us of the condition of the appendages of their possible inflammation and its degree, and in this way it lessens the number of laparotomies and exploratory incisions

11 The same study of the so called galvanic reactions also informs us rapidly (in five to ten séances) of the curability of these inflammatory lesions which the electric current has demonstrated, and in consequence of this it tells us in one case to abstain from operation, while in another it shows an *operation to be urgent*

12 *En resumé* gynecological electro therapeutics, carefully, methodically and patiently applied, instead of being opposed to the marvelous progress of surgery, comes to its aid

Independently, in fact, of the great therapeutic service which it renders every day, electricity serves as a touchstone, it assists us in diagnosis and thus directly serves the interests of surgery, in one case showing an operation to be useless and dangerous, in another that its necessity is urgent

Thus, many of laparotomies, so-called exploratory incisions and mutilations practiced without due deliberation for the relief of rebellious ovarian pain, or for lesions of the appendages of uncertain nature, should be from this time forth, delayed or formally proscribed until all the resources of faradic sedation on the one hand and of the intra-uterine galvanic effect on the other have been tried Experience has abundantly proved these currents to be innocuous, if given with necessary aseptic precautions

NECROLOGY

Frederick M Warner, M D, of New York city, died October 8 He was born in 1857, was graduated from Lehigh University in 1877, and subsequently from the College of Physicians and Surgeons He was house surgeon in the Nursery and Children's Hospital for a year, then went to Europe and took post-graduate courses at Vienna and Heidelberg Since 1881 he had practiced in New York He was a member of the New York Academy of Medicine, and of the boards of several hospitals A widow and two sons survive him

Thomas Keith, M D, LL D F R S, of London, Eng October 9 aged 89 ——J H McLean M D, of Cass City, Mich, October 21 ——Albert Champau, M D, of Detroit, Mich, October 19 ——G M Harris, M D, of Lorain, Ohio, October 24.——S E Clement, M D., of Paris, Tex, October 18, aged 75 ——Judd Packard, M D, of Racine Wis, October 22, aged 25 ——O O Searcey, M D of Temple, Tex, October 19 ——H B Gibson, M D, of Columbia, Mo, October 18, aged 45 ——Abbie J Seymour M D, of Buffalo, N Y, October 17 aged 42 —— T F Owen, M D, of Springfield, Ohio, October 17, aged 64 —— T B Cox, M D, of Frankfort, Ind, October 16, aged 78 ——R L Koepsel, M D of Kansas City Mo, October 16, aged 34 C W Stoddard M D, Ramsey, Ill, October 11

MISCELLANY

An Old Favorite —[For bronchial spasmodic coughs]

℞ Tr benzoin comp	20
Tr opii camph	20
Tr cannabis indicæ	5

M et sig 10 to 20 drops on loaf sugar, as occasion may require

A little Australian boy had been to a Museum of Natural History When he came home he was asked where he had been, and said 'Oh, we've had a lovely time We've been to a dead circus"—*The Outlook*

The Language of a Convalescent —Chief Justice Waite and Judge Hall, of North Carolina, were members of an excursion party on one of the Chesapeake Bay boats When the steamer had fairly got out into the Atlantic, the sea was very rough, and Judge Hall was taken violently with seasickness As he was moaning aloud in his agony, the Chief Justice, laying a soothing hand on his shoulder, said "My dear Hall, can I do anything for you? Just suggest what you wish" 'I wish," said the sea sick Judge, "your Honor would overrule this motion"—*Washington Globe*

Death in Faith-Healer's Family —A certain religionist of New York city, for whom has been claimed powers of healing only a little short of raising the dead to life, has suffered the loss by death from pulmonary tuberculosis of one of his children No one will care to gloat over this faith-healer's domestic tragedy but if some of his blinded adherents could by the sad event have their eyes opened to the limitations of faith cure, no little causeless suffering might be prevented

A Thirty-Ounce Emergency Ration —A dispatch from Washington states that some progress has been made regarding the proposed new emergency ration of the Army The annual report of the Commissary-General of the United States Army says that under direction of the Secretary of War, a board was appointed by the Commanding General of each department, consisting of one officer of the subsistence department, one officer of the medical department, and three officers of the line of the Army, to report on the components of the emergency rations to be carried on the person of the soldier on emergent occasions, where transportation is limited or is not available, and it is believed that it will be possible to provide a ration weighing not more than thirty ounces that will contain sufficient nutriment for the soldier for one day

Ludhiana School of Medicine for Women.—It has for some time been in the minds of missionaries and others, to establish a North India School of Medicine for Christian women, at Ludhiana, in the Punjaub In November, 1894, a beginning was made, and for the last two terms the students have numbered thirteen Five of these are being trained as nurses, two as compounders, and six have entered for the full course of medical study With the exception of two English girls, all are natives or Eurasians The object of the school is to give native and Eurasian girls the opportunity of pursuing a complete course of medical study under the instruction of fully qualified lady doctors, and at the same time to keep them under Christian influence, so that when their curriculum is completed, they may be fitted to minister to the spiritual as well as the physical needs of their suffering sisters, and thus be true medical missionaries Funds are greatly needed for the completion of the passage money, and also for the support of the school Scholarships of £20 per year are also much desired, as the students are mostly unable to pay their own fees

The Samuel D Gross Prize —The second quinquennial prize of $1 000 under the will of the late Samuel D Gross, M D, will be awarded Jan 1, 1900, by the Philadelphia Academy of Surgery The conditions annexed by the testator are that the prize, "shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice, founded upon original investigations, the candidates for the prize to be American citizens" It is expressly stipulated that the successful competitor who receives the prize shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D Gross Library of the Philadelphia Academy of Surgery The essays, which must be written by a single author in the English language should be sent to Dr J Ewing Mears, 1429 Walnut Street, Philadelphia, before Jan 1, 1900 Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer No envelope will be opened except that which accompanies the successful essay The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year The committee reserves the right to make no award, if the essays submitted are not considered worthy of the prize

A Popular Sanitary Tax —Mr H A Andrews has contributed to the October number of *Annals of Hygiene* an account of the Atlanta system of taxation for sanitary purposes The chief sanitary operations for keeping that city sweet and clean are provided for by a house-tax of $3 per year per house, which is known as the sanitary tax With the fund thus derived, and also some other sanitary funds, the source of which is not here stated, the city collects all swill, garbage, night soil, sweepings and other filth, and disposes of them in a salutary manner This house-tax is popular with the average citizen, because he can not otherwise have his premises cared for in the same manner for several times that sum The city is considering reducing the tax to $2 The garbage from the business portion of the city is collected every day, and generally twice a day, especially in the wholesale and market districts In the residence portion of the city, where it is thickly settled, collections are made every day, in other portions, three and four times each week The night soil is taken up from the water closets every week, and none of it is allowed to remain longer It is emptied from the water-tight vessels directly into sealed barrels and driven immediately to the place of final disposition—the crematory The combustible waste at all times is allowed to be mixed with the house and store garbage and operates as a great absorbent, and finally as fuel to burn the more offensive filth This plan is popular with the citizens, as it involves no sorting, nor separation of garbage and trash, or combustible waste The combustible waste and trash are as valuable to the city as cars of coal or other fuel

A Vesical Sequela of Ovariotomy —The *Lancet* for August 24, contains a report of an unusual sequel of an operation for the relief of cystic tumor of the ovary The reporter is Dr Walter Falla, of St Heliers, Jersey, who performed the operation in May, 1894, upon a woman aged 52 years After operation a good recovery was recorded About the end of the eighth month the woman began to complain of pain on micturition, and at the twelfth month there was noticed by her a small amount of blood in the urine In June, 1895, she again consulted her surgeon, and gave all the objective symptoms of urinary calculus, but refused to be examined at that time The pain, however, increased, and two weeks later the sound was passed, and a stone of large size was readily recognized About a week later the calculus was removed by lithotrity The removal of the lithotrite was attended with difficulty and delay, a fact that was subsequently explained when there was found entangled in the blades of the instrument a thick silk ligature covered with a certain amount of phosphatic deposit The ligature had served as the nucleus for the large vesical calculus, and was without doubt the identical ligature that had been used by the surgeon for tying the pedicle during the ovariotomy The unusual features are the entry of the ligature through the vesical walls, with practically no disturbance of the general health of the patient for nine months, and that a foreign body of so considerable size as this substantial ligature should dispose of itself in this situation, when it is beyond dispute in the mind of the operator that the bladder was in nowise injured or endangered in the performance of the operation

Tendon Grafting, a new Operation for Deformities following Infantile Paralysis —At the meeting of the New York State Medical Association, Oct 15, 1895 (*Medical Record*, October 26), Dr Samuel E Milliken, Surgeon-in-Chief of the New York Infirmary for Crippled Children, and Surgeon to the Infants' and Children's Hospitals, presented a boy 11 years of age upon whom twenty months before he had successfully grafted part of the extensor tendon of the great toe into the tendon of the tibialis anticus muscle, the latter having been paralyzed since the child was eighteen months old The case which was presented showed the advantages of only taking part of the tendon of a healthy muscle, which was made to carry on the function of its paralyzed associate, without in any way interfering with its own work The brace which had been worn since 2 years of age was left off, the patient walked without a limp, the talipes valgus was entirely corrected and the boy had become quite an expert on roller skates Dr Milliken predicts a great field for tendon grafting in these otherwise hopeless cases of infantile paralysis, who heretofore have been condemned to the wearing of braces all their lives

How to Read Your Journal —Not every physician knows how to read a medical journal to the best advantage With its numerous readers, with diversified tastes to which to cater, and the vast field from which to cull its topics, it would indeed be strange if all parts of the journal were alike interesting to all The technical discussion of an intricate operation is not of great moment to the busy practitioner, the treatment of pertussis does not interest the oculist, nor the description of the varieties of cataract the gynecologist, and the medical man who attempts to read a journal through, irrespective of its particular value to himself, wastes his time and fails to get good ofttimes from any portion of it. Memory is treacherous in most of us, the thing we want most to remember is often soonest forgotten, and we strive in vain to recall that particular fact which so impressed us as we read the paper Now this may all be obviated by the employment of a system in reading Do not try to remember all that you see, but glancing through the pages note the articles that concern you and with a careful reading note in a book kept for this purpose where the information is contained and where the article may be found, should you in the future desire aid upon this point Such a book, an Index Rerum carefully indexed, is a library in itself and always ready of access, is an invaluable aid in suggestive therapeutics, in difficult and obscure cases, and in all literary work The work of the *Index Medicus*, whose loss we mourn, can be done for each individual with the expenditure of so little effort and time that it is strange the method is not more universally adopted —*Atlantic Medical Weekly*

Illinois State Board of Health —In making provision for the ordinary and contingent expenses of the State government, the Illinois Legislature appropriated for the State Board of Health for salary of secretary, $3,000, for necessary office expenses, including expenses incurred in attending meetings of the board, and in making sanitary inspections, $2,000, for chief clerk, $1,800, for clerk, $1,150, for stenographer, $720, and for incidental expenses, $330—all per annum It also appropriated the sum of $10,000, as a contingent fund, to be used only with the consent and concurrence of the Governor, upon the recommendation and advice of the board, in case of the outbreak or threatened outbreak of any epidemic or malignant disease, such as Asiatic cholera, smallpox, yellow fever, or to defray the expenses of preventing the introduction of such diseases or their spread from place to place within the State, and in suppressing outbreaks which may occur, and in investigating their methods of prevention, also special investigations when required by the necessities of the State, any necessary expenditures from this sum to be paid on the order of the president of the board, attested by the secretary and approved by the Governor

A Costly Hospital for Contagious Diseases —One of the new hospitals for the infectious sick of London is known as the Fountain Hospital It is concerning this institution that the *Sanitary Record* regrets to note that a dispute has arisen between the great Local Government Board and the powerful Metropolitan Asylums Board "Strictures have been passed," says the *Record*, "by the former against the latter, generally as to the policy to be adopted in dealing with any outbreak of infectious disease which may occur, such as necessitating increased accommodation for the reception of patients being provided with all possible speed, also, specifically, in relation to the expenditure incurred in the erection and equipment of the temporary Fountain Hospital The Local Government Board complains that, whereas the temporary hospital at Tottenham, which was intended to receive 456 patients, cost £119 per bed, the temporary Fountain Hospital to accommodate 406 persons, has resulted in an expenditure of £288 per bed, that the cost of the latter has involved a charge upon the rates of £128 000, that the expenditure has been excessive, that the items of expense should have been scrutinized with great care and vigilance by the managers, and that the architect should not have been given full power in the erection of the Fountain Hospital A lengthy letter to this effect was recently forwarded by the Local Government Board to the managers of the Metropolitan Asylums District, and at a meeting of the latter, on October 3, an even more copious reply to those comments, forwarded on the 2d inst, to the Local Government Board, was read and passed The managers of the Metropolitan Asylums District, in reply to the Local Government Board, dissent entirely from the latter's opinion that they were not justified in leaving the matter, which involved such a large expenditure of public funds, in the hands of one man, and they state that any interference on their part with the discretion of the architect would not only have been imprudent, but that it would have led to confusion and delays, and would probably have added to rather than diminished the cost As to the expenditure, the managers point out that, so far as the extra cost is due to the expedition with which the hospital was constructed, they are quite unable to regard themselves as in any sense responsible, the hospital had to be constructed within a certain period, and this necessitated overtime to the extent of finally all night work, and even on Sundays It is further submitted that, having regard to all the circumstances of the case, and allowing for the additional cost paid for speedy construction, good value has been obtained in the Fountain Hospital, which 'is well planned and arranged and well built, and will last for many years" In conclusion, the managers state that they regard the strictures as undeserved and uncalled for, and state that the course pursued was the only one possible under the circumstances

Therapeutics Without Drugs —In a recent address delivered by invitation before the Lehigh Valley Medical Association, Dr Solomon Solis Cohen, of Philadelphia, directed attention to the fact that drug giving is not essential in our therapeutics in very many cases, and, as a rule, should be made to play a subsidiary part Acknowledging their usefulness in proper hands and under proper circumstances, the too great frequency with which drugs are resorted to encourages patent medicine taking and amateur prescribing In very many cases, even of acute disease, recovery will take place under proper care and watchfulness, without any drug taking whatever Both in acute and in chronic cases, many of the ends for which drugs are given can be better and more safely reached through the use of what may be termed natural or hygienic remedies namely, heat and cold, air, water diet, rest, exercise, including under the latter head, massage and electricity As the evolution of the human being has been achieved through action and reaction, with and in a certain environment, so action and reaction under specially adapted environments may modify physiologic and pathologic processes in such a manner as to assist in recovery from disease In this connection the effect of climate upon diet, and of altitude upon the respiratory and the circulatory apparatus is worthy of consideration, and also the circumstances and conditions in which diet climate and altitude may be made use of in therapeutics It is not necessary to go from home in order to secure many of the benefits of atmospheric change The inhalation of compressed and rarefied air by means of suitable apparatus may in Dr Cohen's opinion, be used to develop the lung and influence the circulatory organs, in the great majority of cases, so as to bring about recovery from pulmonary tuberculosis and afford great relief in emphysema, dilatation of the heart and other pathologic conditions in which the process has gone too far to permit a true cure Likewise, the use of heat and cold in subduing inflammations (as in pneumonia, certain diseases of the joints, chronic rheumatism, and the like), the use of cold water in typhoid fever, in neurasthenia and other nervous affections, the rest-cure, the treatment of pulmonary, cardiac, and other affections by suitable exercise, and the application of massage and electricity were briefly explained He believes that blood-letting is a useful therapeutic measure which should be resorted to more frequently than is the present custom, as in many cases it is preferable to the use of drugs The fundamental thought of the whole lecture was that by studying the means through which nature has brought the human organism to its present condition, endowed it with the power of resistance to climatic vicissitudes and inclemencies of the weather, as well as the ability to resist conditions of disease by automatic cell action, the physician may learn how to employ similar means in aiding the natural processes of resistance and recovery Although, while doing this, much assistance may temporarily be given by the timely and skillful use of drugs, it is a mistake to make them the sole dependence, and the lecturer called upon teachers and writers to lay greater stress upon those therapeutic measures other than drugs, which had been and always would be used by the best physicians

Hospital Notes

THE new St Vincent Hospital at Green Bay, Wis, was dedicated October 4 ——The monthly report of the Protestant Hospital at Columbus, Ohio, shows that there were forty-four patients admitted, and forty-six discharged during the month of September, leaving in the hospital October 1, twenty-five patients The annual report of the St Luke's Hospital at Utica, N Y, shows that there were 387 patients treated in that institution during the past year ——The annual meeting of the Women's and Children's Hospital Association of Syracuse, N Y, was held October 18 The report showed that 241 patients were treated during the year —— St Joseph's Hospital, at Memphis, Tenn, was dedicated October 6 ——The common council of Janesville, Wis, have voted to appropriate $500 a year to the Oak Lawn Hospital, a private charitable institution of that city, in consideration of the hospital receiving all city charity and emergency patients

Society Notes

THE annual meeting of the Mahoning County, Ohio Medical Society was held at Youngstown, Ohio, October 16, ——At the annual meeting of the Wayne County, Mich, Medical Society, the following officers were elected President, E B Smith, Vice-President, W R Henderson, Secretary, Frank S Hough, Treasurer, C Henri Leonard ——A quarterly meeting of the Fox River Valley Medical Association was held at Oshkosh, Wis, October 22 The annual meeting will be held at Green Bay, Wis, January, 1896 ——A regular meeting of the Northern Berkshire Medical Association was held in Springfield, Mass, October 17

Louisville Notes

RODMAN —Dr W L Rodman has returned from a four weeks' stay in Colorado where he went in search of health, much improved

DEATH REPORT —Sixty seven deaths have been reported during the past week Of these, 35 were males and 32 females, 53 white and 14 colored Diphtheria and typhoid fever caused 4 deaths each, scarlet fever 1, pneumonia, consumption and organic heart disease caused 6 deaths each, The contagious disease ordinance was not mentioned at the recent meeting of the general council

PALMER —The following invitation was issued by the Louisville Surgical Society to the physicians of Louisville New Albany and Jeffersonville

"The Louisville Surgical Society requests your presence at the Edward R Palmer memorial meeting Saturday evening the twenty-sixth of October, Eighteen Hundred and Ninety-Five, at eight o'clock, Alderman's Chamber City Hall, Louisville Ky"

The speakers were chosen by the Society from the faculties of the four medical schools as follows Kentucky School Dr J M Mathews, Louisville Medical College, Dr A M

Cartledge, Hospital College, Dr L S McMurtry, University of Louisville, Dr J M Bodine The ten minute addresses will be published in the Journal at an early date

St. Louis Notes

Weekly Mortuary Reports —The death rate for the week ending October 26, was 19 per 1000 The total number of deaths during the week was 204, as compared with 178 during the preceding week and 168 during the corresponding week of last year Births reported, 176

Contagious Diseases —During the week ending October 26, the following cases were reported diphtheria, 167 cases, 15 deaths, croup, 23, 18 deaths, scarlatina, 6 cases, typhoid, 12, 4 deaths, measles, 5 cases Thus far during October, 579 cases of diphtheria have been reported, which indicates the prevalence of the disease when it is compared with the epidemic of 1886, when 690 cases were reported during the month of November The high death rate among the cases of croup recently reported points to the need of greater accuracy in diagnosis and shows a failure to make use of the facilities afforded by the board of health for that purpose The board is investigating one case of diphtheria which was treated by a woman who professed ability to cure the disease A physician was called in only as the child was dying

At the State University measures are being taken to produce diphtheria antitoxin after the German method The work is in charge of Dr R E Graham, the newly-elected professor of bacteriology It is proposed to furnish the remedy at cost The project is under the supervision of the State Board of Health

The Saturday and Sunday Association is preparing for its annual charitable collection for the benefit of the charitable hospitals of this city The Saturday collection takes place on November 30, the Sunday collection on December 1 The work is conducted by committees of the Association, the members of which undertake a personal canvass of the various business interests, trades and professions On Hospital Sunday, collections are taken in all the churches The work of the Association is entirely non-sectarian, and the distribution of the money realized is apportioned to the hospitals, in accordance with the percentage of charitable work done during the preceding year

St Louis Medical Society —The program for October 26 included two papers on osteo-myelitis, and one on the use and abuse of uterine curetting

At the Commencement of the Rebekah Hospital Training School October 22, Dr I N Love made a very happy address to the graduates and Dr B M Hypes presented the diplomas The lively interest taken by the public in the education of nurses was well attested by a large audience

Dr A C Bernays, it is reported has at last received $5,000 as his fee for his operation upon the wife of the paranoiac, Duestrow Professor Bernays made an attempt to extract the bullet fired by the insane husband into his wife's brain, and succeeded in prolonging her life for a time His fee was placed at $15,000, but the compromise to $5,000 was finally effected

The Marion-Sims College of Medicine has signalized its prosperity and progress by the purchase of a large addition to its real estate The new ground gives the college nearly 200 feet on Grand Avenue with 258 feet on Carolina Street The new ground is acquired with a view to erect a large hospital, an enlarged dental department, and a laboratory

Washington Notes

Medical Society of the District —At the meeting of the Medical Society held on the 23d inst, Dr Mary Parsons presented an abdominal bandage for the retention of displaced kidneys She mentioned having treated seven cases Dr McLaughlin read a paper (and mentioned cases) on cycling as a cause of prostatic disease Dr E L Morgan read a paper entitled, "Did Jenner Discover Vaccination?" the paper seemed to prove that he did not Dr Necker presented a specimen of abscess of the liver (multiple) and read the very interesting history of the case

Professor of Clinical Surgery in the Columbian Medical School —Dr James Kerr has resigned the chair of professor of surgery in the Georgetown Medical College and accepted the chair of clinical professor of surgery in the Columbian Medical College

The Garbage Crematory Site —The Commissioners of the District have approved the Smith System Crematory for garbage, and have decided to locate the plant at the corner of 23d and Winter Streets The work of construction will be begun at once

Commissioners Report to Congress —The report of the Commissioners to Congress is completed and contains the following estimates two sanitary and food inspectors, who shall be veterinary surgeons, who shall act as inspectors of live stock, dairy farms, etc, at $1,500 and $900 respectively, an increase of $750 for the support of the chemic laboratory is asked Six new sanitary and food inspectors at $10,000 are recommended For the collection and disposal of garbage and dead animals, $57,000 For the purchase of a site and building for isolation hospital for the treatment of minor contagious diseases, $49,000 To prevent the spread of scarlet fever and diphtheria and other minor contagious diseases, including the maintenance of a bacteriologic and disinfecting service, $10,000

Washington Asylum including Hospital	$ 78,485
Government Hospital for Insane (St Elizabeth)	101,016
Emergency Hospital and Central Dispensary	15,000
Columbia Hospital including repairs ($5,000)	29,000
Children's Hospital	14,000
Homeopathic Hospital	9,250
Washington Hospital for Foundlings	6,000
Freedmen's Hospital	56,000
Eastern Dispensary (including $10,000 for grounds)	11 000
Washington Home for Incurables	3 000

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from October 19, 1895, to October 25 1895

Major Charles B Byrne, Surgeon, leave of absence granted is extended three months

Capt William H Arthur, Asst Surgeon, is granted leave of absence for one month

Capt James E Pilcher, Asst Surgeon, extension of leave of absence granted on surgeon's certificate of disability, is still further extended two months on account of sickness

Capt Ogden Rafferty Asst Surgeon, is relieved from duty at Benicia Bks Cal and ordered to Ft Bliss, Texas, for duty, relieving Major Clarence Ewen, Surgeon

Major Clarence Ewen, Surgeon, upon being relieved from duty at Ft Bliss Texas, will proceed to San Francisco, Cal and report to the president of the retiring board for examination

PROMOTION

Capt William H Corbusier, Asst Surgeon, to be Surgeon with the rank of Major, Oct 17, 1895, vice Cronkhite, retired from active service

RETIREMENT

Major Henry M Cronkhite, Surgeon, Oct 17 1895

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending October 26 1895

Asst Surgeon J C Rosenbleuth, to instruction at the Naval Laboratory.

ORIGINAL ARTICLES

PRACTICAL POINTS GAINED IN THE TREATMENT OF ONE THOUSAND CASES OF INSUFFICIENCIES OF THE OCULAR MUSCLES

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY J WALTER PARK, M D
Late Clinical Assistant Royal London Ophthalmic Hospital Ophthalmic Surgeon Harrisburg Hospital Children s Industrial Home and Home of the Friendless
HARRISBURG PA

As the title suggests, my paper is entirely on practical points gleaned from a rather extensive experience in the correction of errors of refraction I examine the ocular muscles of every case that I refract and when any muscular insufficiency is discovered, a record of it is made The subject of heterophoria or insufficiencies of the ocular muscles has become one of such vast importance that I hesitated for some time, wondering whether I had sufficient experience with a large enough number of cases to justify me in expressing an intelligent opinion In looking over my case book I find a record of about a thousand cases, of which I kept rather accurate notes, and I think the results obtained will support the views I entertain upon this subject After all, it is following up one's cases and watching the results for several years afterward that gives us the experience worth placing upon the records of ophthalmology My notes of cases include all muscular insufficiencies, those which I considered should only have general hygienic treatment, those who should have hygienic treatment as well as their errors of refraction corrected combined with the use of prisms Of all my cases I find about 75 per cent of them insufficiencies of the external recti, 25 per cent of the internal, and but two-thirds of 1 per cent of all the other ocular muscles Insufficiencies of the external recti, were most frequent in low degrees of hypermetropia and hyperopic astigmatism, averaging about 70 per cent and about 30 per cent of the interni Insufficiencies of the interni and externi in myopia and myopic astigmatism occurred in about 6 per cent of all the cases

I will consider the management and treatment of these cases under the following classification 1, those occurring in hyperopia and compound hyperopic astigmatism, 2, those occurring in myopia and compound myopic astigmatism, 3, those occurring from constitutional, paralytic, and reflex causes

Under the first classification the majority occurred in cases ranging from + 25 astigmatic, to a + 75 either hyperopic or compound hyperopic cases The degree of variation ranging from 5° to 3° in the majority of cases The insufficiencies occurring in refractive errors from + 75 D to +6 D generally range from 3 to 20° of deviation The majority of cases occurring in the lower refractive errors, ranging from 5° to 3° were no doubt due to spasm of the ocular muscles, and were generally relieved by correcting the errors of refraction, and proper outdoor exercises, and in those cases in which I did use prisms, it was generally only for a few weeks at the longest, when they would finally be more comfortable without them I am now speaking of average results

I wish to impress the fact that I obtained good results in most cases of moderate degrees of insufficiencies, by correcting the errors of refraction, and the advice of complete rest of the eyes for close work for some time, outdoor exercises and general tonic treatment In patients with nervous temperaments, one-thirtieth gr strychnia, and the triple valerianate pills, three times a day did very well in many muscular insufficiencies varying from 5° to 3° I have seen a case of esophoria of 20°, reduced to 6°, within two weeks, from outdoor exercise alone, when no close work was done during that time This patient has been doing continuous close work with ease for the past three months, with a 3° prism, but has no errors of refraction I find very few muscular insufficiencies exist among patients who lead outdoor lives, such as farmers, ironworkers, lumbermen, etc Operative measures are seldom necessary in the majority of muscular insufficiencies

A music dealer, who is myopic and reads music almost constantly, came to me nine months ago with an exophoria of 30° diplopia, and mentally very much distressed, caused by the condition of his eyes I wanted to perform a tenotomy, but he would not allow it I then advised complete rest from close work, and outdoor exercise I did not see him for seven months He then came to my office feeling quite comfortable, no diplopia, and at his usual occupation again

I think tenotomies are necessary in but few cases, and then only where diplopia exists, the insufficiency of a permanent character, suffering considerable, and all other remedies fail In those varying from 3° to 15°, the majority of cases found relief in prisms (combined with their refractive errors corrected) correcting from one-half to two-thirds of their insufficiency Some of these cases when they are obliged to continue at their usual occupation, find relief for from six months to two years, when you generally find their muscular insufficiency has increased and operative measures may be necessary, or they will be obliged to stop their close work This, most patients can not afford to do, and something must be done to relieve them, or you lose your case Exercising with prisms has met with but partial success in my practice I find that the majority of patients will not follow out one's instructions at home, properly, and to come regularly to the office to have it done, incurs an expense which most of them can not meet plying this muscle, just as we may have isolated paralysis of single pairs of muscles in the larynx supplied by the recurrent laryngeal

Thus, the one case in which refraction was Em had had lues some years before Anti-luetic treatment instituted cured the case It seems but reasonable to suppose that lues can affect a muscle which we know is, by weight and measurement, the weakest of all ocular muscles

When after a reasonable delay, medical treatment does not suffice, we must resort to surgery, not to tenotomy of the depressor of that eye or even of the sound eye, but either to advancement of the superior rectus at fault, or tenotomy of the sound one Nowhere is sufficient stress laid upon this Noyes advises tenotomy of the antagonistic muscle and generally that of each eye, when speaking of paralyses of the externi and interni, but says nothing about this special form Possibly, we think no one would be foolhardy enough to try tenotomy of the inferior rectus to remedy the evil

The *first* case of this series, who was rid of his troublesome diplopia by just such an operation, I believe was a case of paralysis of the superior rectus This, on the face, would appear feasible, as these two muscles are antagonistic in just that sphere of action which causes the asthenopia All agree ordinarily, *that some form of prismatic correction* will suffice, especially when coupled with muscular exercise

In the minor affection of this muscle, just a word in conclusion I doubt if any careful worker fails to test muscular equilibrium in every case of asthenopia I am sure you will find many cases of vertical deviation amounting to as high as 1 5° and, indeed, I have seen several higher than this, in which the correction of the refraction sufficed Just how common this is, I should hesitate to say, but in my last hundred cases of asthenopia, I found twelve with various degrees of hyperphoria, and of these but one required correction for a hyperphoria of 1 5°

Though my experience is naturally somewhat limited, I am still at a loss to understand how it is that some men find such frequent and urgent need for correction of hyperphoria of even 25° I should not for one moment wish to be understood as doubting the accuracy of this observation, I simply do not meet with such cases

Finally, it seemed that the American ophthalmological world was in danger for a time of going heterophorically mad It appears that the pendulum is beginning its backward swing, and we may now be approaching a more rational conception of this subject

My attention was called during the session to a condition of diplopia which is normal to every one That is, in near vision, even as far off as one to two meters, you can produce a diplopia very much like that of the paralysis of the superior rectus but the images are not tilted, and this diplopia disappears in the distant vision test, which is not the case where a true paralysis of the muscle is present

800 Madison Avenue

When Physicians can not Testify in Pennsylvania —No person authorized to practice physics or surgery, it has been enacted in Pennsylvania, shall be allowed, in any civil case, to disclose any information, which he acquired in attending the patient, in a professional capacity, and which was necessary to enable him to act in that capacity, which shall tend to blacken the character of the patient, without his consent

---

REPORT OF THE COMMITTEE ON THE PREVENTION OF BLINDNESS FROM OPHTHALMIA NEONATORUM

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10 1895

BY *LUCIEN HOWE, M D*

BUFFALO, N Y

At the meeting of the AMERICAN MEDICAL ASSOCIATION held in Milwaukee in 1893, the following resolution was unanimously adopted by the Section on Ophthalmology

WHEREAS, There are in the United States several thousand who have become blind because of ophthalmia neonatorum; and

WHEREAS, This unfortunate result is largely preventable, being due to the neglect of nurses and midwives, therefore

Resolved, That it is the sense of this Section of the AMERICAN MEDICAL ASSOCIATION, that a committee of five be appointed by the chair to urge in all parts of the country, by personal application, by circulars to physicians and legislators, and by blank forms of a desirable law, such legislation as will tend to lessen the blindness caused by this disease

Upon careful consideration, it was decided that the following would be about the best form of a law to suggest for adoption in the various States, this being almost the same as that which had already been passed in New York, Maine and Rhode Island:

SECTION 1 —Should one or both eyes of an infant become reddened or inflamed at any time after birth, it shall be the duty of the midwife, nurse, or person having charge of said infant, to report the condition of the eyes at once to some legally qualified practitioner of medicine of the city, town, or district in which the parents of the infant reside

SEC 2 —Any failure to comply with the provisions of this act shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months, or both

SEC 3 —This act shall take effect on the first day of June, eighteen hundred and ninety one

Early in December, 1892, a circular letter was sent to all of the prominent ophthalmologists throughout the country, asking their cooperation in obtaining such legislation They were requested to call the attention of the several State medical societies to the importance of the subject, and to ask these societies to give their approval of such a law in order that committees could present the matter to the Legislature with the strongest medical indorsement

About four hundred and ten of these first letters were sent to ophthalmologists and to leading physicians in various States, and the replies, together with suggestions in regard to the legislation, necessitated the writing of two hundred and fourteen additional letters Of all of these, copies are on file of the letters sent and the replies also have been retained

The accompanying is a tabular statement of the most recent data that can be obtained, in regard to the condition of legislation for the prevention of blindness, each State being given alphabetically

To sum up the results, they may be stated as follows

The law had, in substance, already existed in three States New York, Maine and Rhode Island

Since then, it has passed both houses and been signed by the Governors of six States Minnesota, Ohio, Maryland, Connecticut, Missouri, and New Jersey

It is therefore in operation in a population of over eighteen million Moreover, a sufficient number of

* The law passed the Senate but was defeated in the House Will be presented again

convictions have already been obtained to show the efficiency of some such measure when prosecution is properly carried out

It has been presented and referred to committees in five States Pennsylvania, California, Michigan, New Hampshire and Illinois

It has passed one House and been defeated in the other in four States Louisiana, South California, Iowa and Indiana In each of these, the committee intend to present it next year

In four States Arkansas, Kentucky, North Carolina and West Virginia the bill has been indorsed by local or State medical societies but no effort made to present it to the Legislature

In the other States, no official action has been taken in regard to it It is important to note, however, that more than eighty ophthalmologists and other prominent physicians have promised in writing to give their coöperation and hearty assistance to such legislation, and, with the plan thus thoroughly organized in so many portions of the Union, it is not too much to hope that a few years will find this law or its equivalent on the statute books in nearly every State in the Union. The committee desires thus to report progress.

Signed, LUCIEN HOWE, M.D.,
GEORGE M. GOULD, M.D.,
G. C. SAVAGE, M.D.,
HENRY GRADLE, M.D.

The above report with the table represents the information obtained by the committee at the time the report was made. It should be said, however, that since then practically the same law has been passed in Pennsylvania and Illinois, so that at present it exists among a total population of over twenty-eight million people.

183 Delaware Avenue, Buffalo.

NOTE.—The above report with the table represents the information obtained by the Committee at the time the report was made. It should be said, however, that since then practically the same law has been passed in Pennsylvania and Illinois, so that at present it exists among a population of over twenty-eight million people.

THE RELATIONSHIP BETWEEN THE EYES AND THE BRAIN.

Read in the Section on Ophthalmology at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7-10, 1895.

BY JAMES A. LYDSTON, M.D., PH.G.

Oculist and Aurist to St. Joseph's Hospital, Chicago; Lecturer on Ophthalmology and Otology, Chicago College of Physicians and Surgeons; President of the Alumni Association, Chicago College of Pharmacy; Member of the American Medical Association, the Chicago Academy of Medicine, etc.

CHICAGO.

The frequency of eye disease originating from brain lesion is all sufficient to render an attempt to trace a closer relationship between the eyes and the brain justifiable and merits, by reason of its utility in ocular and brain diagnoses, very careful consideration. If we are dealing with structural ocular changes we are often able to define the etiologic factor at once, but at times we are confronted by functional disturbances which are but vaguely explicable; under such circumstances if we could only view the eyes as a component factor of the cerebral and cerebellar mechanism, obscurity in diagnosis would vanish. I have always regarded the eyes as nothing more nor less than prolonged bulbous expansions of the optic nerves with altered anatomic characters to meet the requisites of their physiologic necessity, viz., to formulate and receive impressions of the external world and, carrying the analogy a step further, we find that the optic nerves are but the telegraphic media of conduction extending from the perceptive center or brain and finally terminating in their bulbous expansions, the eyeballs,—so that the eyes may be justly regarded as the terminal filaments of the optic nerves, and we accordingly note that sources of peripheral irritation excite central phenomena, while *per contra*, in the majority of instances the initial pathologic process appears in the brain and travels downward along the nerve or its sheaths, as in descending neuritis arising from cerebral tumor or other central morbid process.

Anatomic data are likewise corroborative of an intimate association of the eyes and the brain, for notwithstanding the attempt to separate the optic nerve fibrillæ into separate and distinct bundles, we find that there is here and there along the nerve a complete fusion, so that it is only possible, according to Uhthoff, to separate the macular bundle as a distinctly central bundle in close proximity to the chiasm. See too, how intimately the optic nerves are connected with the brain. This connection is chiefly a threefold one, for we have a large part entering the external geniculate body, another part the thalami optici and pulvinar, and another the anterior corpora quadrigemina; thence from these so-styled primary optic ganglia, fibers are traceable to the posterior third of the internal capsule midway between the lenticular nucleus and optic thalamus, extending under the name of Gratiolet's optic radiation to the cortex of the occipital lobe, and chiefly to that part of the cortex which is styled the cuneus, terminating, finally, in the ganglion cells of the cortex within a region which has received the appellation of the optical cortical area, or visual sphere of Munk, which in turn is intimately connected by means of bundles of associating fibers with the cortex of the frontal, parietal and temporal lobes of the same side, and we are in a position to infer from the connection of homonymous parts of the cortex of the two sides by means of commissural fibers, the chief of which is the corpus callosum, that an intimate association between the various cortical elements is maintained. Then too, the semi-decussation of the optic nerves seems to have been designed by Nature among her allwise provisions as a means of creating a more intimate relationship between the eyes and the brain.

We note further that the eye undergoes degenerative change when its central connections are divided, and again, ascending atrophic optic nerve changes supervene when destruction of the eyeballs has occurred which, following the experiments of Gudden, I have myself fully verified in experimenting on rabbits, destroying one or both eyes and observing the course of the consequent atrophy. And while such changes are only approximate as applied to man, still opportunity to determine this question postmortem has been afforded several observers, and their findings are fully in accord with the generally accepted conclusions applicable to nerves. We know that when a nerve is divided in an adult, degeneration ultimately extends as far as the terminal network, implicating those ganglion cells whose axis cylinders extend through the same nerve, and later other groups of ganglion cells become involved as a result of contiguity, extension of some inflammatory process or otherwise,—and here it may be well to emphasize the changes that are consequent upon destruction of both optic nerves, or obliteration of the chiasm; necessarily they are bilateral, *i. e.*, in all cases in which a lesion lies on the central side of the chiasm, the ocular manifestations are symmetrically exhibited in both eyes, while asymmetrical phenomena in both eyes, as well as monocular visual defects, are referable to a lesion in the optic nerves proper, or anteriorly to the chiasm. If the lesion divides the chiasm vertically we have hemianopsia as illustrated by Weir Mitchell's case, cited in the *Journal of Nervous and Mental Disease*, 1889, p. 44, in which an aneurysm had completely divided the chiasm in the median line and caused blindness of both inner retinal halves. With respect to the importance of either one of the three primary optic ganglia in the rôle of the visual act, it is unfortunate that investigators have reached no concordant results, owing to the rarity of clearly defined examples of isolable lesions implicating one or the other of the primary ganglia, and the fact that we are unable to extend our experimental researches to the human family Crossed hemianopsia has been known to follow obliteration of a single pulvinar, while destruction of the anterior corpora quadrigemina has ensued without perceptible visual impairment, although I believe Gowers is authority for the statement that choked disk in which blindness was not a conspicuous feature has followed injury of the anterior corpora quadrigemina, however, the general consensus of opinion of investigators is that the anterior corpora quadrigemina preside over movement of the extrinsic ocular muscles, their nuclei being intimately associated with them

If we consider the comparatively small surface area of the retina, we are surprised to find that the bundles of optic nerve fibrillæ are so numerous, and again, when we consider the minuter and all-important papillo macular region we note that the most important conducting fibers are here disposed, and as we are justified in assuming that the papillo-macular bundle is formed by an agglomeration of optic nerve fibrillæ, each one of which has an intimate as well as individual connection with the brain, we must conclude that the eyes are simply outlying cerebral structures, so placed as to meet the exigencies of their function, and in cases of sympathetic irritation which in many instances precedes general ophthalmitis, we are able to readily appreciate the rationale thereof, although in accordance with the definitive experimentations of Deutschmann, and conforming to the most recent bacteriologic research, we ascribe the occurrence of sympathetic ophthalmitis to the transmission of germs through the medium of the optic nerve sheaths, rejecting the theory of nerve irritation After accepting such an intimate association of the eyes and the brain, it would not be unreasonable for us to expect that ophthalmoscopic investigation would at once reveal the cause of cerebral and sequelar ocular changes, but unfortunately such is not the case, for the reason that the cerebral and optic nerve circulation is governed by the amount of blood, not alone in the carotid, but depends upon the entire circulation in the circle of Willis, which in turn depends upon cardiac tone, and while increased or diminished blood pressure in the carotid might excite retinal hyperemia or ischemia, it would be no positive criterion as to the nature or gravity of the pathologic cerebral change However appropriate the attempt to define a coarse relationship between the eyes and the brain, we are still confronted by the necessity of tracing the distribution of the optic nerve fibrillæ in the brain, or, as it is usually styled, the origin of the optic nerves, in order to explain many of the symptomatic ocular phenomena characteristic of morbid cerebral and cerebellar processes Unfortunately, we are still unable to assume a positive stand in this direction, and yet that which is positively known in this regard enables us to classify many changes with a reasonable degree of assurance Thus we know with respect to cortical visual disorders, *i e*, those which are situated on the central aspect of the primary optic ganglia, heretofore mentioned in Gratiolet's optic radiation and in the cortical portion of the occipital lobes, that 1, central disturbances necessarily induce homonymous ocular phenomena, 2, ophthalmoscopic manifestations are absent, 3, involuntary light reaction is present, even if optical memory pictures are not elicited We find that destruction of the cuneus in man, induces marked hemiamblyopia in the opposite half of the visual field, or the same effect as the obliteration of the entire cerebral cortex, which proves a uniform distribution of all optic nerve filaments, all theoretical reasoning to the contrary Schaefer, Munk and others have demonstrated by experimentation upon animals, and clinical data support their findings, that feeble electrical stimulation of the occipital cortex causes conjugate ocular movements to the opposite side, upward when applied posteriorly, downward when applied anteriorly, which indicates that the brain exercises control of voluntary motor ocular movement and presides over orientation, enabling us to ascribe the proper position of an object in the visual field

Embryology also teaches us that there was primarily a very intimate relationship between the brain and the eye, and that the eye has virtually evolved therefrom, for the eye develops from an invagination from both sides of the primitive cerebral vesicle, which invagination is styled the primitive ocular vesicle, and remains attached by means of a broad pedicle which subsequently contracts and forms the optic nerve. This pedicle is enveloped by the ectoderm which at the apex of the ocular vesicle becomes thickened, constituting the first germ of the lens which ultimately is reduplicated by reason of the more speedy development of the ectoderm and appears as a pouch like eversion which subsequently closes, forming a sac—the lens vesicle The retina is likewise derived from the primitive ocular vesicle and is therefore regarded by many as a remote part of the brain, and in accordance with embryologic development we are certainly at liberty to regard the eye as a whole, as a cerebral appendage Again, when we consider how intimately associated the ocular mechanism and the nervous system, as a whole, appear to be, as fully borne out by the various symptomatic phenomena such as cephalalgia, migraine, vertigo, visual hallucinations, asthenopia, various types of hyperesthesia, scintillating scotoma, reflex phenomena, and very often in cerebral hemorrhage we find transitory homonymous hemianopsia in the visual field of the side opposite to the hemorrhage —we must conclude that the connection between the eyes and the central nervous system is very close In cases of cerebral hemorrhage too, while occasionally there may be ophthalmoscopic findings due to the hemorrhage, more frequently do we find pathologic changes in the eyes that arise from the same cause as the cerebral hemorrhage Thus neuritis, albuminuric retinitis and neuro retinitis are signs of similar brain changes, while retinal and subhyaloid hemorrhages are indications of a general atheromatous tendency

LYMPHANGIOMA CAVERNOSUM OF THE ORBIT

WITH AN ORIGINAL CASE

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md., May 7 10 1895

BY S C AYRES, M D

CINCINNATI, OHIO

Mr C, age 53, was first seen May 15 1894 At that time there was a well marked proptosis of the right eye, which he said had been coming on for about three years He had had no pain in the eye or the orbit He could count fingers at

3′ but the inner field seemed to be more sensitive than the outer field There was well marked optic neuritis Motion of the eye was unimpaired The diagnosis given was a probable sarcoma beginning in the apex of the orbit

He has generally enjoyed excellent health and has been an active business man Family history his father died at 70 and his mother at 83, one sister living and in good health, and two sisters deceased—one from a malignant growth and one from childbirth It was impossible to detect any growth around the rim of the orbit and it seemed evident that the growth, whatever it might be, was located in the apex of the orbit and was pressing the eye directly forward

He was not seen again until Nov 26 1894 In the meantime the tumor had grown very considerably, and the proptosis was very marked The eye now stands about 8 mm in advance of the plane of the left eye Motion upward was limited and the eye diverged, as if pushed out in the axis of the orbit The optic disk was very considerably swollen, and vision was 0 2 Within the past few weeks he has had three severe attacks of pain in the head, lasting several hours each time, and during them he had a tingling sensation in the right side and some delirium There has also been at times a well marked mental hebetude He became listless and sleepy, and lost interest in everything around him When his wife read to him, he would fall asleep or would lose interest in what was read, or in conversation He has had a large number of nasal polypi removed within the past year, but there was no evidence of any malignant growth in the nasal fossæ The increasing exophthalmos and the mental hebetude and the attacks of pain in the head made him decide to submit to surgical interference for relief There is no evidence of any growth in the orbit from palpation nor was there any bruit or pulsation He was told that an attempt would be made to remove the tumor and save the the globe, if such was found practicable, after its size and character had been sufficiently obtained in the first steps of the operation The external rectus was first severed, leaving a stump on the sclerotic, so that it could be used for reuniting the muscle in case the tumor could be removed without sacrificing the eye After getting an opening sufficiently large for me to make an exploration with my finger, I found that I had to deal with a large elastic tumor, which grew within the muscular funnel The optic nerve was on its anterior surface and put greatly on the stretch In view of the injury to all the ocular muscles and optic nerve from an attempt to remove so large a tumor, I decided to enucleate the tumor and globe together The growth filled the bony walls of the orbit so closely that there was some trouble in detaching it, but this was finally accomplished and the optic nerve severed at the very apex of the orbit

Macroscopically, the tumor presented a whitish appearance and was firm but elastic The optic nerve was attached to it by bands of connective tissue It measured 35 mm in length, the diameter of the outer end was 22 mm, and that of the inner end 13 mm

It is now five months since the operation, he has had no pain in the head, and the mental dullness and apathy have entirely disappeared He takes an active interest in everything around him, and has regained his former mental activity This has been one of the striking features of the case

The microscopic examination was made by my friend, Dr J E Greiwe, whose letter I copy

"*Dear Doctor* —I have examined the specimen which was removed from the orbital cavity, and I send you a few preparations stained with Boehmer's *hemotoxylin* I do not think there can be much doubt about the nature of the growth, and, while one would certainly be justified, from a macroscopic examination of the tumor, in coming upon the suspicion of ecchinococcus, yet there is nothing to justify the diagnosis microscopically There are no hooklets, no characteristic membrane, etc The new growth, if you may call it in the strict sense of the word a new growth, is characteristic of lymphangioma Macroscopically, you will notice that the preparation shows many small cavities The tumor itself is composed for the most part of lymphoid cells, both large and small, the cavities are for the most part lined with an imperfect layer of endothelium, and within these cavities are numerous lymphoid cells lying about loosely There are no traces of blood vessels, and there is no evidence of glandular formation Lymph vessels are numerous and large, and these larger ones are lined with a perfect layer of endothelium The examination agrees also with the clinical history of the case I think the trouble originated from an occlusion of one or more lymph channels causing an engorgement, which in the course of so long a time resulted in a mass of this size My diagnosis is lymphangioma cavernosum

Very sincerely,

(signed) J E Greiwe"

The literature at my command shows only two similar tumors and probably a third The first one is by Forster, in *Gracfe's Archiv.*, vol xxiv, 2, p 107 The second is by Wiesner, *Gracfe's Archiv*, vol xxxii, 2, p 205, and the third by Dunn, *Am Jour*, *Med Sciences*, 1894 There may be other cases of similar character, but I have not access to them In consideration of the rarity of the disease, I have made translations from the above cases and have added notes from Ziegler and Michel

In Forster's case the tumor was situated within the funnel of the ocular muscles, as was mine, and was about the same length but broader In this case, however, there was no mental disturbance and no pain In mine, the mental hebetude seems to have depended on the influence of the tumor The tension of the tumor on the optic nerve must have been very considerable, as the nerve was found lying *over its anterior* surface We can not calculate from other statistics, as they are wanting, the probable or possible influence of such a stretching of the optic nerve on the brain, but in my case they seemed to stand to each as cause and effect

In Wiesner's case the tumor was located between the globe and the lower outer edge of the orbit, and was ovoid in shape and movable

In Dunn's case, the patient was a leukemic boy, 8 years of age, and the tumors were above the eyes and attached to the orbital arches, and there was no impairment of motion or vision

There is an apparent inconsistency in the vision of the eye when examined in May and November At the first date he could count fingers at only 3′ and in November he had a vision of 0 2 I can only account for the difference by the variation of pressure on the optic nerve

1 Professor R, *Gracfe-Sacmisch*, vol vi, Berlin, page 700, (quoted from Forster, *Arch fur Ophthal*, xxiv, 2, p 108) The only case reported up to date (1875) is reported by Forster "For the past ten years, Nicholas B has had a steadily growing protrusion of the eyeball Status V = movements of the hand and one foot The skin of the lid is red, and the veins varicose The globe is strongly abducted, and with difficulty pressed backward Movements of the globe are greatly interfered with, especially upward and inward Palpation of the inner side of the orbit gives one the sensation of a slightly movable, soft, in places nodular tumor about the size of a nut Pulsation distinct, auscultation negative Ophthalmoscopically white atrophy of the optic nerve with but slightly filled vessels Clinical diagnosis sarcoma fibromatosum orbitæ Enucleation of the globe and tumor Healed in six days No recurrence Macroscopic examination within the muscular funnel to the inner side and below the globe, was found a soft elastic tumor 37 mm long and 35 mm broad, which was inclosed in a capsule On section the entire tumor showed itself permeated by spaces of various sizes, between which are broad bands of fine connective tissue Microscopically, the inner walls of the alveoli are lined with endothelial cells The walls themselves are formed by layers of connective tissue fibers, between which are spindle cells which are arranged

concentrically to these cavernous spaces The spaces contain numerous lymphoid cells, whereas the fibrillary walls show large quantities of elastic fibers and blood vessels "

The clinical character of this tumor coincides most remarkably with that of a cavernous angioma The slowness of its growth, its painlessness, its seat within the muscular funnel, the retention of a certain amount of movement in all directions, its soft elastic consistence, which the specimen showed, in short, the only symptom which was lacking and which in this instance was not sought for is the swelling, to have made this a complete picture *We must, further, not forget the most important fact, that this even in itself rare form of tumor, a cavernous lymphangioma, is found here for the first time in a tissue in which, anatomically, up to the present time, no true lymph vessels have ever been found*

Owing to this being a single isolated case which up to date has been reported as occurring in the orbit, the writer (Berlin) is prompted to give it thoughtful criticism This would certainly not be possible if the microscopic examination of the alveolar contents had given us a completely convincing result But he simply states "The areolar spaces contained numerous lymph corpuscles " It certainly would have been of great importance to know whether there had been any other morphologic elements present The fact, as the author states, that the specimen was preserved for one and one half years in Muller's fluid and alcohol before the microscopic examination was made, might certainly give us a reason for the difficulty in recognizing red blood corpuscles The course seems to be an exceedingly slow one Prognosis as regards the general condition is good As a rule, as a result of pressure on the optic nerve or on the globe or both, it leads to atrophy even destruction of the globe Therapy extirpation

2 Ziegler's "Pathology," vol ii, page 304 Published 1891 "The angiolymphaticum, or the lymphangioma, bears to the lymph system exactly the same relation, that the angiom does to the vascular system It consists principally of a dilatation of lymph vessels, which is at times associated with a hypertrophy of the lymph vessel walls and the tissue between them It is possible to differentiate between a lymphangioma simplex or telengiectasia lymphatica, and a lymphangioma cavernosum We must still mention a third form, the lymphangioma cystoides As one may see from the nomenclature, the configuration and size of these dilated lymph vessels varies greatly In the most pronounced change, veritable cysts are formed The contents of these spaces is mostly a light and clear, exceptionally a milky lymph The condition is partially congenital, partially acquired The congenital lymphectasies are found in various forms, as in the tongue, (macroglossie), the dental arches, the lips (makrocheilie) in the skin (nævus lymphaticus), on the neck (hyroma colli congenitum) the labia majora, etc It is not unfrequent to find the lymphectasie in the skin as an acquired condition, for example, on the thigh and on the scrotum At times they form extensive, circumscribed, fluctuating tumors (Fig 157) The ectatic and cavernous lymph vessels show thickened walls, and have their seat more especially in connective tissue and fatty tissue, owing to extension of this cavernous development of lymph vessels over a large surface of the subcutaneous tissue of the skin and may cause an elephantiasis-like disfigurement of the part Not infrequently the tissues which lie between this growth also undergo a hypertrophy If these cutaneous lymphangioma burst, a lymphorrhea ensues Not infrequently we find hyperplasia of the skin and other organs complicated by the ectasie of the lymph vessels of the skin In very exceptional cases, chylangiome of the intestinal wall and the mesentery have been found, and exceedingly seldom, cystic lymphangiome of the peritoneum "

3 Michel, *Augenheilkind*, 1890, page 649 "Cavernous angioma and lymphangioma may occur primarily in the orbit They are most frequently found in the muscular funnel, less frequently between the latter and the bony wall The latter is the case when the tumor has extended by growth, and this most frequently extends toward the roof of the orbit The lymphangioma, it may further be stated, occurs in the latter years of life (about the fortieth year) and may then occur primarily between the muscular funnel and the edge of the orbit The symptoms at first may be very slight, simply causing a slight impediment to free movement, thus leading to diplopia As the tumor grows, the eye is pushed forward The surface of the tumor as a rule is smooth, sharply defined, movable and compressible Anatomically, the tumor is made up of connective tissue, the alveoli are lined with endothelial cells, contents, a serous fluid containing lymphoid cells *Lymphome have been observed in the orbit at the same time with others in the lid, in leukemia* " (See page 11)

4 Thos J Dunn, case of leukemia with rare lymphoid growth of orbits and parotid gland The *American Journal of Medical Sciences*, 1894 "Boy 8 years, highly leukemic Growths in the orbits were crescentic above the eyes and not firmly connected with the lids beyond the nasal side of orbits and extended to the external canthus, and were firmly attached to the orbital arches Not painful Considerable exophthalmus Motions of eyes not much interfered with Eyes healthy otherwise Vision normal No autopsy allowed "

5 B Weisner, "The Lymphangioma of the Eye," *Graef Arch* , vol xxxii, B 2, page 208 Case seen in November, 1885 History patient 43 years old Tumor of lower lid Since past two months, diplopia Status weak hypermetropia Complete loss of function of right rectus inferior Between globe and lower outer edge of the orbit is an ovoid movable tumor, about the size of a hazelnut, hard consistence, smooth surface No exophthalmus Diagnosis fibroma of the orbit in tissue between the peri orbital and rectus muscle Operated one week later, November 13 Incision made parallel to the lower orbital edge just below the same, and the tumor, which was loosely connected with the peri-orbita and muscular funnel, was easily peeled out without loss of blood Healed by first intention Patient discharged on fourth day (*a*), *macroscopic examination* tumor 77 mm long, 9 mm high, 5 mm thick On incision a serous fluid escaped Tumor showed a cavernous structure with relatively large and some smaller spaces, showing a striking likeness to the cavernous structure of the corpus cavernosum of the penis Tumor was covered with a thin fibrous sheath (*b*), microscopic examination made partially on teased preparation, partly on sections stained with hemotoxylin The lax tissue around the tumor is concentrically arranged, rich in fat and blood vessels, whose

walls are hypertrophied The fat is infiltrated with lymphoid cells Accordingly the tumor is to be designated as a cavernous lymphangioma of the orbit He then quotes Forster's case. The mode of development of these tumors They must belong to the class of new formations which take their origin from embryonal tissue . This follows from some unknown cause

We must assume, in the foregoing cases, that in the orbital tissue at some point, the development starts from (the lymph vessels have not as yet been demonstrated) the germ of the mesoderm or embryonal formative cells In such a new growth all such tissues may be found which are destined to be developed from the mesoderm That in any special case any particular type should predominate is not to be wondered at In one case it assumed the character of a cavernous lymphangioma, which is rich in connective tissue, has many hollow spaces filled with lymphoid cells The formation of blood vessels keeps pace with the formation of connective tissue, which they nourish In a later stage muscular fibers develop The formative material, however, has been present from the beginning, consisting undoubtedly of a portion of the spindle cells interspersed in between the connective tissue framework The arrangement of the muscular fibers is so far regular, in that they arrange themselves in bundles, otherwise, they follow no regular type The pressure which results from the growth of the tumor explains the inflamed condition of the vessels of the fibrous capsule, which appear to have developed from the cellular tissue of the orbit The inflamed condition of the capsule is demonstrated by the hypertrophied condition of its capsule The hollow spaces within the tumor are of very irregular form This is the result of the outgrowth of processes, which meeting each other from opposite sides lead to the formation of new spaces, and this going on will gradually lead to increase of the tumor

This tumor must be differentiated from the cavernous angioma, and in so doing I must confine myself to a clinical differential diagnosis

The cavernous lymphangioma has no characteristic clinical picture, so that we can show but indirectly by the clinical history that they are not cavernous angioma Based on a case of v Graefe (*Graefe-Saemisch,* vol vi, p 708) Berlin describes the principal clinical features of the cavernous angioma 'The spontaneous increase and diminution of the swelling, which can also be induced mechanically Its full, elastic, but at no point hard consistence, the almost totally intact muscular movements, its seat in fatty tissue, its extremely slow development, its painlessness and lastly the otherwise good condition of the patient "

Not a single one of the symptoms was present in this case (as also in Forster's case) The increase and diminution of the swelling was entirely wanting Forster's case showed exophthalmus, nor was the consistence like that described by v Graefe It was hard, which could not be the case in a tumor that was changing its size and elastic Still it was very difficult to form a correct idea as to the consistence of a tumor, especially when palpating a tumor in the orbit Then again, there was not in our case a totally intact muscular condition, for we found impairment of the external rectus In Forster's case, in which the tumor was inside the muscular funnel, the movement was interfered with in all directions If this last symptom were always found lacking in cavernous angiome, and in both the other cases was found present, this could be explained by the different anatomic character of the tumors For the angiome is compressible, hence, any interference with muscular movements can be easily overcome, whereas in the lymphangiome this can not occur, hence the interference with the muscular action The seat of the disease, the painlessness and general condition of the patient are general symptoms and do not enter into the differential diagnosis

The other objection which Berlin makes to Forster's case I do not consider as proved The fact that this is an isolated case simply goes to prove that it is a rare affection and it is possible that some of the cases which have been described as fibroma of the orbit were of this nature It seems strange that Berlin is not satisfied with the statement that "the spaces were filled with lymphoid cells and contained no other morphologic elements," and again his remarks about the preserving value of Muller's fluid. Examination of specimens which had been preserved for many years in Muller's fluid demonstrated the fact that it does preserve the red blood corpuscles beautifully

Berlin seems to be of opinion that lymphangioma can only occur where lymph vessels are present I here once more point to the mode of development of these tumors, and will further add Wegner's theory. (*Langenbeck Arch* xx) Wegner arrives at the following conclusions

1 Lymphangioma may develop from already existing lymph vessels, which become dilated as a result of stasis, owing to closure of larger lymph vessels, hence, as a result of ectasie with hyperplasia A case of this kind of so-called capillary lymphangioma has been described by Ben Israel (*Uber Lymphangioma Mag Dis Würzburg,* 1885)

2 A second mode of development is not from preexisting lymph vessels, but from newly formed lymph vessels, which are the result of an active proliferation of endothelium which already exists—homoplastic neoplasm

3 A third form is mentioned by Wegner, in which there is also a new formation of lymph vessels, which develop from connective tissue, granulation tissue. which is the result of the dilatation of spaces gradually taking on the character of lymph-carrying spaces—heteroplastic neoplasm

In speaking of the subject of ectopia lentis before this body of oculists, it is not my purpose to review the literature upon the subject nor to discuss in particular the symptoms or treatment Each and every one of you doubtless has met with the various forms of ectopia lentis—spontaneous, traumatic and congenital In my practice within the last twenty years I have seen almost every form of luxation of the crystalline lens I have seen the lens as it were a drop of oil in the anterior chamber, I have seen it extruded through the sclera lying beneath the conjunctiva, I have also seen it entirely expelled from the eye through the cornea Only a few days ago when attempting to evert the lid of a baby with ophthalmia neonatorum, the lens popped out on the cheek through the ulcerated staphylomatous cornea I have found the lens partially dislocated from its bed, swinging backward and forward like a shutter on its hinges Quite frequently have I found it luxated into the vitreous and floating there I remember one case in particular, where the lens had been broken and thrust into the anterior chamber by an osage orange thorn, and the attending surgeon was about to remove the eye, mistaking the comminuted lens in the chamber for panophthalmitis

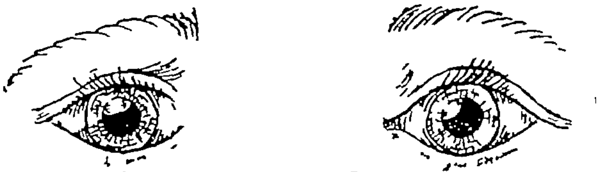
I call to mind several cases of luxation of the lens into the anterior chamber, which for want of proper diagnosis and timely treatment had provoked suppurative iritis and glaucoma Several cases I have had of so called spontaneous luxation into the vitreous, but invariably they were in myopic eyes or cases of synchisis, but all these you have also had, and it is not of them I wish to speak I want to call your attention especially, gentlemen, to two cases which are in my opinion rare or unique The first is that of traumatic luxation of both lenses at one and the same time in an individual whom I saw at Edgar Brown's clinic at Liverpool, Eng, September, 1887 The patient was a woman of middle age On each eye the lens was seen resting upon the sclera beneath the conjunctiva a few mm from the inner and upper border of the limbus There was a rupture of the sclera about 8 mm long between the superior and internal rectus, parallel with the limbus, and some 3 or 4 mm from the sclero corneal junction The injury was caused by a clutch of the fist during an altercation between the woman and her son in law I speak of this as a most rare accident, both eyes having been identically and simultaneously injured But it is to my second case I especially call your attention This case is that of congenital ectopia lentis in a family of nine children, the Vogle family of Leavenworth, Kan, seven of whom were thus afflicted, while the other two had not the slightest displacement of the lens In each of the seven, the lens of each eye was displaced in some direction from one third to one half or more of its width With the pupils dilated, one could readily view the fundus of the eye, either through or at one side of the lens With the indirect method, two images of the fundus could be seen at one and the same time The lenses all seemed slightly opaque, and the edges were all dark, appearing as a black curved line dividing the pupil, this line probably was due to the total reflection and not to opacity In each case there was iridodonesis and the lens could be seen swaying slightly to and fro None of the children complained of or admitted of having monocular diplopia

Of the seven afflicted, there were three girls and four boys, ranging from 4 to 19 years I made a careful examination of both eyes of each child, taking the vision with and without glasses, making a drawing of each eye, illustrating the direction of the luxation and amount I have had a half tone made of these drawings which I hand you They will show better than words can tell, the appearance of each case examined In most of the cases you will notice that the displacement is outward, in some slightly upward and outward, in one alone the lens of both eyes is displaced toward the nasal side

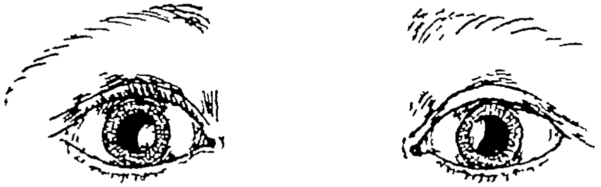
JOSEPHINE AGE 19

WILLIAM AGE 12

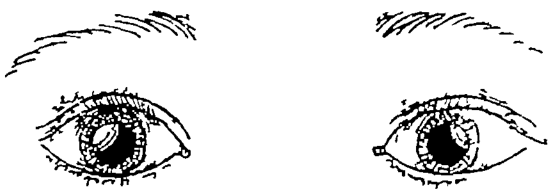
HERMAN AGE 4



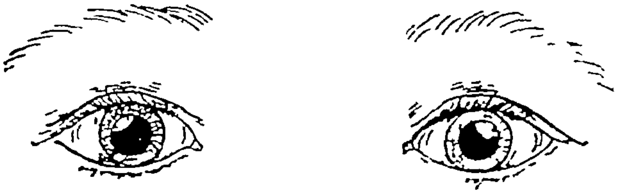
EMMA AGE 15



FREDDIE AGE 10



MINNIE AGE 16



THEODORE AGE 8

In No 1, the oldest, Josephine, vision without glasses was 20 200 Glasses gave but little improvement

No 2, Minnie, aged 16, V R E =20 200 V L E =20-200 with + 3 50 vision was increased to 20-60 For reading she required +12 Pupillary distance was 60 mm

No 3, Emma, age 15, V R E = 5 200, V L E = 8-200, +11 D s gave best vision

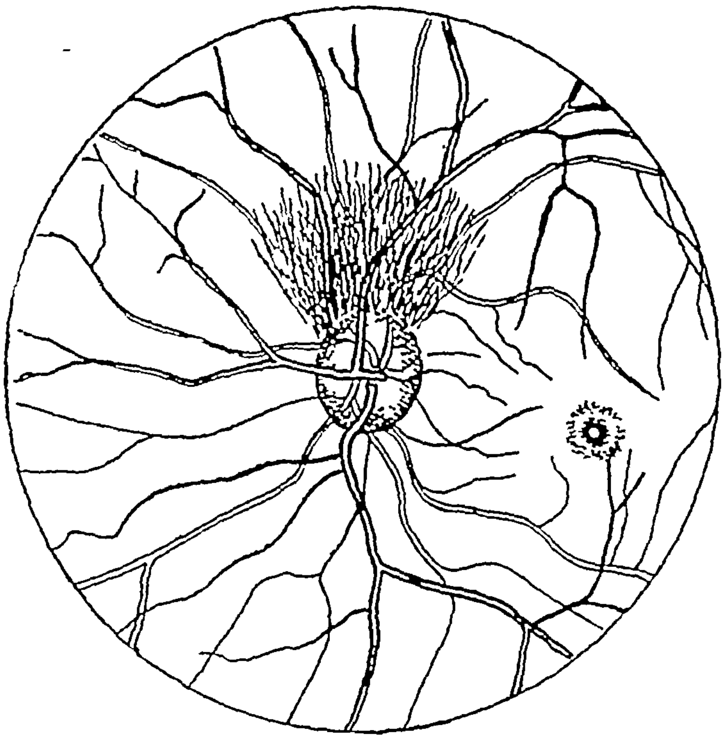
No 4, Willie, age 12, V R E =8 160, V L E = 6-160, +11 gave best vision

No 5, Freddie, age 10, V R E = 12 160, V L E = 12-160, Gave + 13, P D, 60 mm

No 6, Theodore, age 8, V R E = 3-200, V L E = 3-200, + 11 gave best results

No 7, Herman, age 4, vision as near as I could tell was about 8-200 of either eye

As the diagram indicates, you will see that in the case of Josephine, the lenses were displaced horizontally outward In the case of Emma, the lens of the right eye was vertically upward, while that of the left eye was upward and inward In Theodore, both lenses were displaced upward and outward In Freddie, both lenses were shoved inward, toward the nose This is the only one with displacement inward of both eyes In the case of Minnie, the lens of the right eye is displaced upward and outward, while that of the left is more nearly horizontally outward In the case of William, the right lens is horizontally outward and the left is upward and outward In the youngest child Herman, age 4, there is but slight displacement and that is outward and upward in either eye He seems to have the least amount of vision of any The other two children—Louisa, age 18, and Bertha, age 6, who are not in the group had 20 20 of either eye, but under the mydriatic it was revealed that they were hyperopic each to the amount of 3 D Louisa had the medullary sheath or gray fibers of the optic nerve showing in the left eye



Louisa, age 18

The mother of these children is 40 years old, and examination showed nearly a normal eye or a very slight amount of hyperopia The father is dead, but the wife testified to having noticed that her husband had something shaking in his eyes and that he was very near sighted He was a tailor and worked constantly at the bench up to his death without glasses The shaking in the eye she noticed was probably a tremulous iris and from this fact and that he was myopic we may naturally conclude that he was afflicted with ectopia lentis The father was Swiss and the mother German and they were no blood relation

Now the question that interests me especially, in this group, is the etiology, and also why seven out of nine should inherit the anomaly and two should go free, and why all but one should have the displacement outward You may say that it is due to an arrest of development, then we naturally inquire of what part of the eye, not of the lens, for certainly in these cases the lenses were of the natural size and shape If you say that coloboma of the iris or of the retina is due to an arrest of development, or that cleft palate or bifurcated uvula are due to an incomplete union, I can more easily understand that, they being at the median line It seems to me that these cases are of special interest from an etiologic stand point and again from the fact that so large a number of the same family are afflicted And were we to explain the etiology, what may we say of the distinction why were most of these children doomed while two escaped?

TREATMENT

In the primary infinitesimal amount of protoplasm from which the body is evolved, there are inherent all the potential elements that may go to form the perfect being in all its minutiæ, but if these potential elements are vitiated by abuse, by profligacy, by dissipation, by debauchery, or by excesses and intemperance in any direction the impress in some way is most sure to be visited on the prenatal child These freaks and anomalies are, then, the direct consequences of the violation in some way of the great laws of nature and whereas it is not in our power to reintegrate the present, we should ever be on the alert by judicious and timely advice, to exert our influence in protecting future generations against vitiated inheritancy, that they may not be dwarfed or crippled in their physical or mental development

1235 Grand Avenue

ENCHONDROMA OF THE CARTILAGE, UPPER LID

Read in the Section on Ophthalmology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md, May 7-10, 1895

BY PETER D KEYSER, M D
PHILADELPHIA PA

In 1888 Mrs P, age 58, presented herself at my clinic at the Wills Eye Hospital with a round lump in the upper lid, which she said had been slowly growing for a year or two No inflammation connected therewith It was hard, solid and firmly attached to the cartilage An incision was made along the lid over the tumor and the convexity of the latter shaved off This was firm, cartilaginous, cutting crisply and of a yellowish white appearance It had all the appearance of a thickened cartilage No microscopic examination was made of the part removed

In 1890 she came back with a much larger return of the growth It was again operated on as in the former method No examination made In 1892 it had grown again and more nodular My purpose now was to try to remove all of the diseased cartilage, leaving if possible the conjunctiva, so as to protect the cornea To do this the edge of the lid was carefully slit up, and as much as could be of the cartilage down to the conjunctiva removed This seemed to do very well for awhile, but after six or eight months it began to develop again quite rapidly, growing along the whole cartilage, taking upon itself a well developed nodular form, and with a small open sore on the edge of the lid, the whole having the appearance as in the accompanying figure

Operative influence was again necessary to remove the unsightly looking lid and to relieve distress, so, on Sept 11, 1894, the edge of the lid was carefully slit and the skin dissected up so as to expose the whole growth The whole cartilage of the nodule on the nasal side was removed with the conjunctiva, while that of the temporal side was dissected out as much as possible, leaving the conjunctiva

After the operation Dr Currie, chief resident surgeon and acting curator of the hospital preserved what was removed, for preparation and microscopic examination After some time he presented me with some carefully prepared slides and called my attention to a number of cells such as are exhibited in enchondroma After very careful examination it was decided that the growth was enchondromatous formation, and as it was a simple outgrowth from the normal cartilage, might come under Virchow's term of ecchondroses

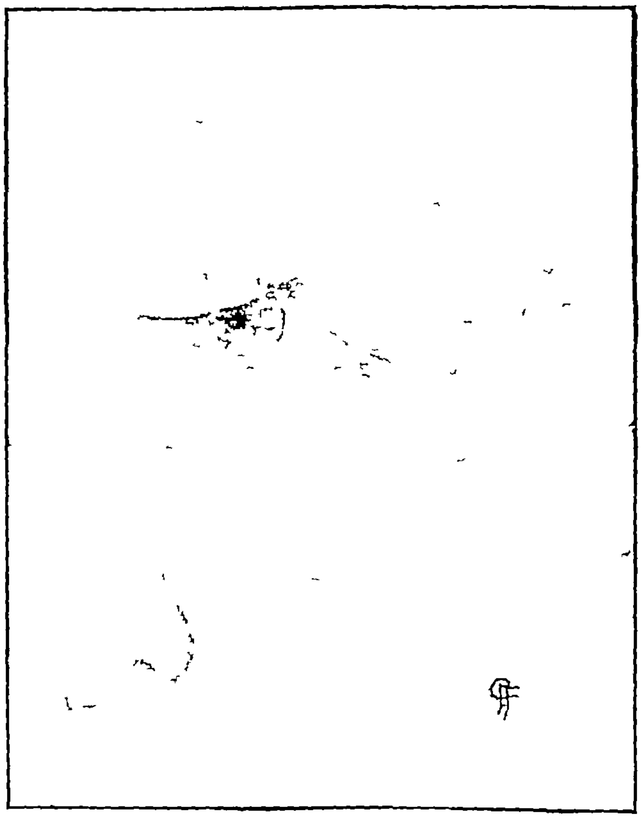


Figure 1

Dr Clarence P Franklin was kind enough to make a drawing of the eye just previous to the operation (Fig 1) and also to make the accompanying sketches from the slides under the microscope, showing the fibrous and cartilaginous nature of the specimen There were well developed walls with the cartilaginous cells lying therein, some separated, while in others they are packed closely together There is also glandular tissue See accompanying drawings

The character of growth in this place seemed somewhat strange and to me new, and search has been made in all the works on ophthalmology in my library to find if such a growth in that part has been noted An examination of all the text books on ophthalmology published in English, German and French, so far has failed to find any report of such a growth except in Fuchs In the chapter on the tumors of the lids he writes "In consideration of the complicated structure of the lid, in which such a manifold variety of tissues take part, it should not surprise us that the most dissimilar kinds of tissue should at times come under observation As rare occurrences there have been observed fibromata, enchondromata, etc , of the sebaceous glands (including Meibomian glands and the glands of Krause) of the sweat glands and the glands of Moll "

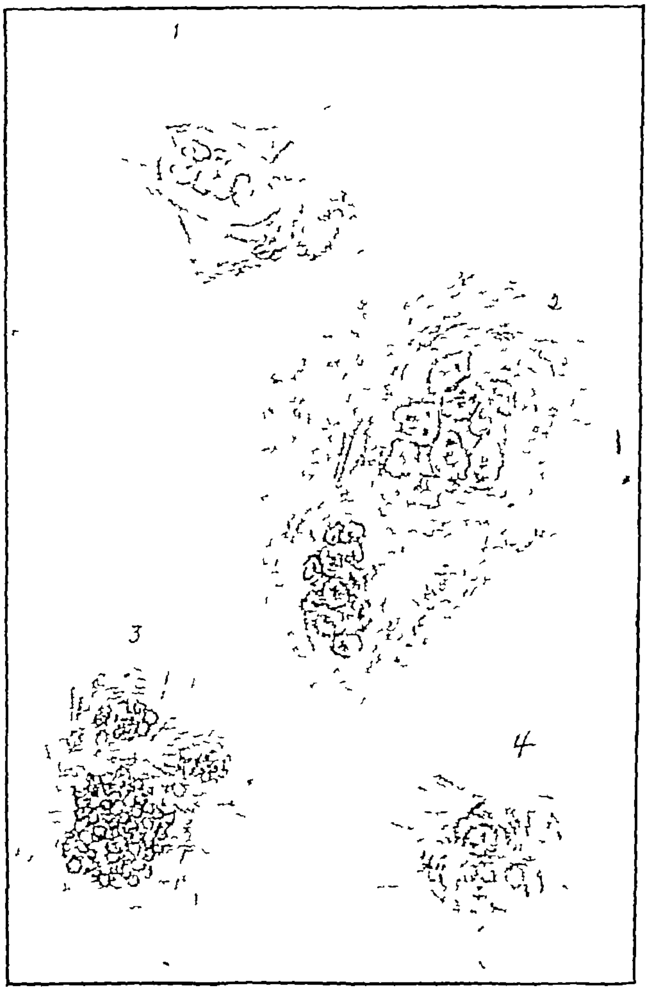

Figure 2

Search has been made in all of the German, French and English ophthalmological journals from their beginning, and no case found reported The *Jahres Bericht*, "*uber die leistungen und fortschritte im Gebiete der Ophthalmologie* of Nagel, and the *Index Medicus* have been looked through and no case reported

Fuchs is the only one so far found, calling attention to the fact of such a growth taking place on the lid I present the case as one of very rare occurrence

Figure 3

NOTE —Dr de Schweinitz writes me that the following in his text book escaped my notice "Rare forms of benign tumors are adenoma of the sweat glands and their follicles, papilloma of the ciliary border and enchondroma *of the tarsus*" He also says, *that his information on the* subject was derived from Fuchs, who appears to be the only one reporting such a case, and Panas also refers to the same, evidently derived from Fuchs"

FORMALIN AS A PRESERVATIVE AGENT FOR EYE SPECIMENS

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the *American Medical Association, at* Baltimore, Md, May 7-10 1895

BY WILLIAM H WILDER, M D

CHICAGO

The use of some of the older hardening and preservative agents especially for eye specimens is accompanied with certain disadvantages

Chromic acid and its salts, as used in Muller's fluid, although eminently satisfactory for hardening certain specimens, such as those containing nerve tissue, so *discolors them* that beautiful macroscopic preparations are difficult to obtain from its use Alcohol and methyl-alcohol, although not discoloring the tissues of the eye, are open to the objection of making the cornea opaque, abstracting the color from the iris, blood vessels, etc, and what is more serious, unless cautiously used, of causing such contraction of the tissues as to almost spoil some delicate specimens Again, Muller's fluid and the alcohols require a considerable time to completely harden the tissues of the eyeball so that it can be satisfactorily mounted These objections do not pertain to *formalin, which is one* of the most valuable preservative agents we have

Formal or formalin is an aqueous solution of formaldehyde, the latter in its original state being a gas resulting from the oxidation of methyl-alcohol As obtained in the market this solution is a colorless, neutral liquid with a specific gravity of 1 080 to 1 088, having a pungent penetrating odor and containing 40 per cent of formaldehyde It is miscible in all proportions with water, so that solutions of different strengths can be readily made

The specimens exhibited here were hardened in a 5 per cent solution, made by using one part of formalin (Schering) and eight parts of water

This strength has seemed to me the most useful, although a weaker solution may be used also with success Hermann, of Erlangen, (*Anatom Anzeiger*, Dec *11, 1893) found that* he could completely harden an organ as large as a calf's heart in a 1 per cent solution in twenty-four hours

N W Alleger, of Washington (*American Monthly Mic J* 1894, xv) is reported as preferring a 10 per cent solution as a hardening agent It seemed to me that some of my specimens hardened in a solution as strong as this, did not preserve the natural colors (particularly *the blood* in *the vessels*) as did those in the weaker solution

The method of procedure is, in brief, as follows after washing the blood from the enucleated eye with ordinary water, it is placed at once in a bottle containing two or three ounces of the 5 per cent solution, where it remains for a few days It will then be found hard enough to bisect In case the eyeball is filled with a tumor or a mass of exudate, it can be cut with a thin razor almost as easily as one would cut an apple, but if the vitreous is present either in the normal or fluid condition it is best to freeze it, so that in cutting, the relation of the delicate internal structures may not be disturbed and the lens dislocated

The part that is to be preserved entire, after thawing in tepid water, if it has been previously frozen, is then placed for twenty-four hours in a 33⅓ per cent solution of glycerin and water, and then for an equal length of time in a 50 per cent glycerin water solution It is then ready for mounting in glycerin jelly after the method of Priestley Smith described in the *Ophthalmic Review*, 1884

This glycerin jelly begins to soften at about 120 degrees Fah, but the formalin may be again used to solidify the gelatin and to make the preparation permanent Before capping and hermetically sealing the cells, they may be placed under a bell jar with a little cup containing a small quantity of the formalin The vapor of formaldehyde that is given off, fixes or hardens the jelly so that it can not be softened by boiling in water or even a soda solution I commonly leave my specimens exposed to this vapor for about twenty-four hours, and then seal by cementing on the cover

Hauser, of Erlangen (*London Therapist*, Aug 15 and Sept 15, 1893), makes use of the formalin vapor for solidifying the gelatin on which colonies of bacteria are growing, thus making permanent preparations of cultures for demonstration

It will be seen in the specimens that the cornea and lens retain almost their normal transparency, at least enough to enable one to note the color of the iris and the whitish pupillary reflex present in glioma The injection of the ciliary vessels is also well demonstrated in some specimens, while the retinal vessels may be fairly well traced even to small branches The tissues preserve their natural color and are not shrunken The retina retains its position better than after hardening with alcohol or Müller's fluid, although in some preparations it will be seen slightly wrinkled

For microscopic work it presents little or no advantage Specimens that are to be embedded in celloidin must go through alcohol after leaving the formalin solution, but the appearance of the cell structures shows that the formalin acts as an excellent fixing agent

Marcus (*Neurolog Centralbl*, 1895, xiv, 4) recommends highly the use of formalin for hardening specimens of the central nervous system, and claims that the results he obtained with the Weigert Pal method of staining nervous tissue hardened in this way were much superior to those of the old methods Whatever its value as an antiseptic or therapeutic agent, it must be conceded that as a medium for preserving and hardening anatomic and pathologic specimens it has not its equal

103 State Street

SOME POINTS REGARDING THE ETIOLOGY AND TREATMENT OF POST-NASAL CATARRH, WITH REMARKS ON THE HYGIENE OF THE RESPIRATORY ORGANS

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7 10, 1895

BY W FREUDENTHAL, M.D

CONSULTING LARYNGOLOGIST TO BETH ISRAEL HOSPITAL VISITING LARYNGOLOGIST TO ST MARK'S HOSPITAL, THE MONTIFIORE HOME, AND THE GERMAN POLIKLINIK, ETC
NEW YORK

There exists for whole nations as well as for the single individual, health and disease, life and death Both are never in perfectly normal conditions of their organic being, in both, out of *small* and *persistent* working noxious influences, lasting dispositions and stationary diseases are developed, which affect here single organs or systems and there a great many or the majority of a nation

And just as certain as deeper causes finally influence the whole body of the individual, making him a sickly type, so the noxious agents affecting a whole people can stamp upon it a more or less distinguishable type of peculiarity and susceptibility to sickness or infirmity (Geigel)

There are some noxious causes which the writer believes prevail more in this country than elsewhere The disease, which we shall discuss in this paper, is post nasal catarrh with all its sequelæ This disease is so frequent in this country that when European authors speak of American catarrh, they mean this affection In this country it is usually spoken of simply as catarrh Now it is the intention of this paper to show that post-nasal catarrh is not such a simple thing as is often believed, and that its causes and effects are to be sought in conditions in which we did not look for them before

The naso pharynx is a cul de sac between the nose and the pharynx, and this situation alone ought to be sufficient proof that it belongs to or is a part of the respiratory, as well as of the alimentary tract Not only because its mucous membrane is lined with columnar ciliated epithelium as the whole respiratory tract, does it belong to this part, but also, *and this is the most important reason*, because it impregnates—I do not say saturates—the inspired air with humidity

That "in the ordinary process of deglutition," as Bosworth says, "it is absolutely necessary that the lower pharynx should be thoroughly lubricated by mucus, in order that the bolus of food shall pass over it without hindrance," and that this mucus comes from the glands of the vault of the pharynx, is, I think, generally accepted

But these glands have in my opinion, another task to fulfill Just as it is difficult to get a bolus down into the esophagus and stomach, when it is not lubricated, just the same difficulty is experienced by inhaling air into the lungs that had not been previously moistened in the upper air passages This moistening process is to a great extent accomplished in the naso-pharynx Yes, I am inclined to assert that the major part of this process takes place in that portion of the respiratory tract

I formed this opinion after repeating the experiments made by Aschenbrandt[1] Already in 1886, Aschenbrandt showed the importance which the nose played in warming as well as moistening the inhaled air As these experiments are of importance for our further investigations, I will mention them briefly here

Aschenbrandt took a U-shaped glass tube which he partly filled with pumice stone and sulphuric acid (See Fig 1) This tube he connected on one side with a straight tube, r^1, which he placed air tight in one nostril The other end of the tube was connected by means of rubber tubing with a glass jar

This jar contained 5 liters of water and was arranged so that in thirty seconds the entire water could flow out Now if we open the clamp at *h*, the water flows out and 5 liters of air will be drawn in through the nose in the following manner through—we will say—the right nostril into the naso-pharynx, into the left nostril, and from there through the glass tube T, to the U-tube, and into the big jar

In the nose and naso-pharynx the air is saturated with moisture, which again is absorbed by the pumice stone and the sulphuric acid in the U-tube, a fact of which we can convince ourselves by touching this glass, which gets warm as soon as the air circulates through it The big jar containing 5 liters=5 000 ccm , is emptied in thirty seconds, i e , corresponding to ten respirations of 500 ccm each

In making this experiment it is better to put a second glass tube *r* into the other open nostril, in order to prevent the strong current of air from closing the nostril Now if we first let the air alone pass through the U-tube and weigh it, and then connect the apparatus with the nose and weigh it again, we can easily determine to what degree the air is saturated with moisture each time

Aschenbrandt and later my friend Richard Kayser,[2] of Breslau, claimed on the ground of these experiments that the air becomes thoroughly saturated with moisture in the nose, while E Bloch,[3] of Freiburg, asserts that the saturation is not complete I have made a great many experiments in the chemic laboratory of Dr H Schweitzer and came to the conclusion that neither is right, but that the truth lies between the two

---

[1] Die Bedeutung der Nase für die Athmung Würzburg 18[illegible]

[2] Die Bedeutung der Nase etc für die Respiration Pflüger's Archiv 1887 page 127 and ibidem 1890

It seems to me that in even apparently normal noses the ability of the mucous glands to give off moisture to the atmosphere varies in different persons and at different times In the majority of cases, my results corresponded very closely or were similar to those of Aschenbrandt and Kayser, while, on the other hand, there were quite a number of apparently just as normal noses, where the gain in weight gave evidence that the inspired air was surely not fully saturated with humidity

A few examples may serve as illustrations Dr L, assistant in the laboratory of Dr Schweitzer, has, as far as I could see by an examination in the laboratory, a normal nose The U-tube weighed before the experiment, 26 4907 grams, after 5 liters of air had passed through the nose, the tube weighed 26 6115 grams, showing an increase of weight of 1219 grams

This volume of air passed through in thirty seconds In one minute we would have

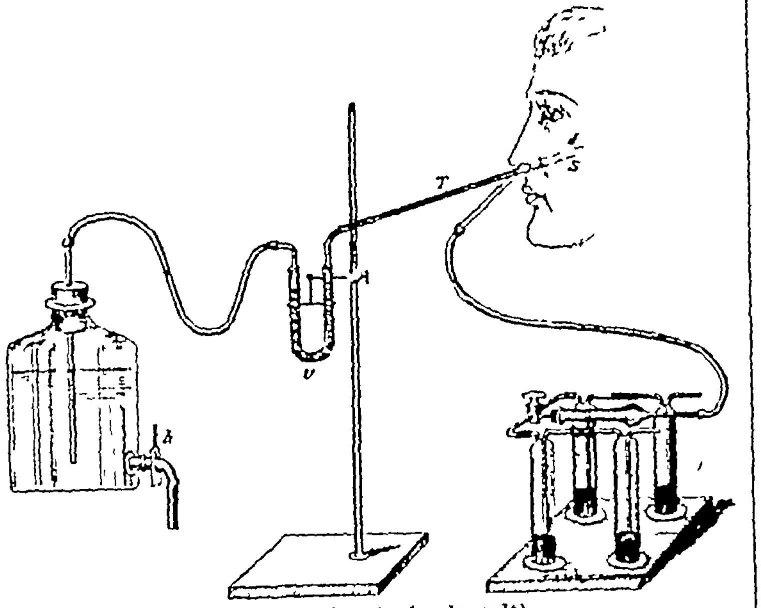

Fig 1—(After Aschenbrandt)

	0 1219
	x 2
	0 2438
In an hour	x 60
	14 6280
In twenty-four hours	x 24
	351 0720

The relative humidity of the air was 48 per cent, and the sum of 351 grams per day would not be in favor of Aschenbrandt's theory, while the next case of a 15-year-old office boy, also with a normal nose, gave the following results

The tube before the experiment weighed 26 6428 after the experiment it weighed 26 8028 grams Therefore increase in thirty seconds, 1600 grams Therefore increase in twenty-four hours, 460 8 grams

The temperature of the room was 68 degrees F, and the relative humidity 48 per cent If I add the humidity which the air gives off in the rubber tube, we would have approximately 500 grams per day, or about the amount necessary to a perfect saturation. These are a few examples taken from a large number of cases that I have experimented upon, but they suffice to illustrate the results

I will now add my modifications, which are twofold first, I examined a number (although not a large one) of pathologic cases, which to my knowledge has not been done heretofore In almost all of these cases I found a diminution of the moisture for the inhaled air, but I will say that here is a large field for further investigations I shall limit myself to a few examples only

Case 1—H S, was galvano-cauterized in his nose repeatedly and is well since Temperature *of the room* 69 degrees F, relative humidity, 48 per cent The U-tube before the experiment weighed 26 455 grams, after the experiment it weighed 26 513 grams Increase in weight in thirty seconds *only*, 058 *grams*, *increase in weight in* 24 hours, 167 04 grams.

We observe at once the immense difference *in this man*, who had been cauterized about four years ago The mucous membrane in his nose was so destroyed that during one day he gave off only 167 grams of water instead of 500 grams

Case 2—Dr S S, has been suffering from hay fever for eight years, but last year he was in Germany and was free from it Temperature of the room 69 degrees F, humidity 48 per cent Weight of the U-tube before the experiment, 27 0055 grams, after the experiment, 27 1095 Increase in thirty seconds, 1040 grams, increase in twenty-four hours, 299 52 grams

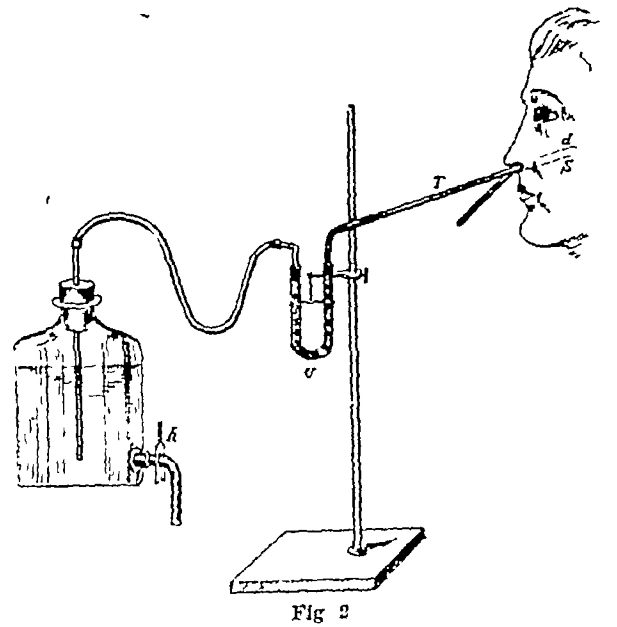

Fig 2

Case 3—Office boy with large adenoid vegetations The temperature of the room and relative humidity the same as above U-tube before the experiment, 26 435 grams, after the experiment, 26 455 grams Increase in thirty seconds, 0 20 grams, increase in twenty-four hours, 57 6 grams

This boy, therefore only gave off about one-ninth part of the normal amount, *i e*, 57 6 grams per day instead of 500 I must state, however, that the obstruction in his retro pharynx was so great that the air could be drawn through the nose only very slowly, and that at the end of thirty seconds only 2 liters of water had flown out of the jar, instead of the usual 5 liters The lymphoid tissue was removed, and a few weeks later the experiment repeated The numbers were quite different

The weight of the U-tube before the experiment was 23 1170 grams, the weight after the experiment, 23 2570 grams Therefore the increase in thirty seconds was 1400 grams, the increase in twenty-four hours, 342 72 grams

The reason why we did not now get the full amount of about 500 grams per day, lies in the fact that very likely the glands in the retro pharynx had not as yet regained their physiologic secretory power

---

[3] Untersuchungen zur Physiologie der Nasenathmung Ztschr f Ohrenheilkunde, 1888, page 215

I could not get a patient with rhinitis sicca to come down town as far as Front Street, where the experiments in the laboratory of Dr Schweitzer had been made, but from the first case of H S, whose nasal mucosa had undergone partial destruction, we can imagine the result in this disease To get very exact numbers I have used in the beginning two U-tubes, which were connected with each other But this increase in weight of the second tube after 5 liters of air had passed it, varied only from 0003 to 001 grams I therefore did not consider it of much importance and used only one U tube afterward

Another series of experiments which I made, consisted in letting *absolutely dry air* pass through the nose For this purpose, I connected the one nostril as before with the U-tube and the jar of water, and the other nostril with Liebig's apparatus, as shown in Fig 2 This apparatus makes the air perfectly dry and free from carbonic acid The results obtained by this method showed the increase in weight of the U-tube to be almost identical with the former ones, consequently the nose gave off in these experiments much more humidity than in the former In other words the nose had not only to bring up this absolutely dry air to the humidity of the air of the room (43–60 per cent relative humidity) which was used in the former experiments, but, in addition, it saturated the air with humidity to the same extent as when the air of the room was used The giving off of water *therefore from the nose was much greater* The bearing of this condition in relation to our subject will be discussed later on

As interesting as all these experiments were, so much did the idea strike me that they were only, to a certain degree, applicable to the physiologic respiration of the healthy man First, the air that we inhale, passes through only one nostril Therefore, if the volume of air be driven through both nostrils, it must gain a proportionate quantity of moisture from going over a larger surface of the respiratory tract Consequently, a part of the moisture gained by driving the air through both nostrils must be deducted in our experiments, hence the Aschenbrandt-Kayser theory that the air in passing through the nose is saturated completely with moisture is not perfectly correct Another reason for this is, that the air is never driven or sucked through the nose with such force as in our experiments In the normal quiet respiration the air goes through the nose, only slightly touching the septum and the turbinated bodies and thus striking the wall of the retro-pharynx, creates a whirling motion which brings the different particles of air repeatedly in contact with the mucosa This causes a longer delay of the air in the retro-pharynx than in any other part of the upper air passages, and in consequence thereof we must expect that the glands here have more chance to give off moisture than elsewhere in the upper respiratory tract Another fact in favor of my theory is the boy with the hypertrophied lymphoid tissue at the vault of his pharynx At the first experiment the air had to remain a long time in the nostrils, on account of the obstruction in the retro pharynx But, nevertheless, the air that passed through was by no means saturated with humidity The gain in weight of the U-tube was, on the contrary, so small that a saturation of the air could not be spoken of After the removal of the lymphoid tissue, when the air could freely pass through the retro-pharynx, the gain in humidity was so much that it almost reached the normal condition Thus we have to attribute a great deal of the work done in saturating the air to the retro pharynx

Now what are the reasons that prevent the retro-pharynx from performing this function? Of the many reasons which might come into consideration, allow me to discuss only two, which I consider of the greatest importance, and which to my knowledge have not been hitherto discussed in this connection The first is the manner in which the houses in New York and other large cities of the United States as far as I know them, are heated in winter, and the second are the so called colds

There are three different ways of *heating* a whole house from one source the first is hot water heating This is of the least importance to us, as it is used comparatively little in this country, although advantages are claimed for it by some reliable firms here and in Boston Scientific investigations, however, of this method regarding our purposes have not been made

The second way of heating houses is by means of steam This has great disadvantages, which most of you have undoubtedly noticed to your own discomfort As a rule, I find that houses and flats heated by this method, are entirely too hot It is nothing uncommon to find a temperature of 80 degrees F, especially where there are small children The people, often very intelligent, think their little ones need much warmer rooms than grown people, and are confirmed in this obnoxious idea by physicians who do not know better Undoubtedly it is difficult to regulate the steam heat according to one's wishes In this connection, Dr John S Billings in his excellent book on 'The Principles of Ventilation and Heating" (New York, 1884) says "The only way to diminish the heat is, to either close the register which cuts off the supply of fresh air, or to turn off the steam from the radiator, which will give an insufficient supply of heat The result is, that the great majority of steam-heated rooms are, during many days in the year too hot, and at the same time have an insufficient supply of fresh air, producing much the same kind of discomfort as an ordinary *hot-air furnace*, although somewhat less in degree"

Whether this last statement is really correct, we will discuss immediately, as we are now coming *to the third and most important* method of heating the hot-air furnace You are all familiar with this method of heating The shaft which conveys the so called fresh air to the furnace, is situated near the ground and usually in close proximity to the kitchen This shaft is so poorly constructed ninety-nine times out of a hundred, that the bad air in the cellar has free access to it The air from these sources is heated in the furnace, and passes into the rooms This impure air of the cellar is warmed, that means it is deprived of the greatest part of its humidity, if not of all of it In this condition of dryness it reaches the rooms wherein we live There it has the effect of drying the already present air and it is evident that the colder the atmosphere is outside and the more we heat our furnace, the dryer will the air become in our rooms Now it has been shown by various experiments that the atmosphere of a room in winter should be kept moderately humid, *i e* it should contain between 50 and 60 per cent relative humidity The lowest point should never go down below 40 per cent while we still feel pleasant at a relative humidity of 70 per cent , even 75 or 80 per cent are not considered unhealthy

Now gentlemen I have tested it quite often during the last two winters, and I have never seen a relative humidity of 50 per cent in New York houses When the outside temperature was about 30 degrees F , I have never seen even 40 per cent! The highest point reached was 30 per cent , but 25, 20, even 18 per cent relative humidity, was nothing unusual when the weather was very cold and when this lasted for any length of time, so that the rooms were not at all or very little aired

Casimir Wurster, who studied these conditions in New York also, found that sometimes in private dwellings, hotels or theaters the relative humidity goes down as low as 10 per cent I made such investigations systematically during the winter of 1893-1894 in different hospitals of this city I give you below, the data found at the Montefiore Home for chronic invalids, a hospital which is located hygienically better than most hospitals in this city, and where I found the highest percentage of humidity Of course I took into consideration that these investigations were made at a time when the weather was already milder and the windows and doors could be opened Although as I said, the results were the best obtained, you will see by looking over the tables, that even in this hospital the relative humidity seldom reached 40 per cent , i e , the lowest amount necessary for our comfort Generally it was below this point, *ergo*, detrimental to the inmates Here are the data which Dr Fraenkel, the house physician of the home had the kindness to assist in procuring

We see from this data, that the relative humidity once went down to 19 degrees in the smoking room where generally more people are together, and that it only exceptionally reached 40 degrees, although the outer temperature was already mild and windows and doors could be kept open often How very detrimental this state of affairs is, will be clearer to you if we compare it with the same conditions in summer In summer a relative humidity of 85, 90, or 95 per cent is nothing uncommon in this neighborhood and this when the temperature reaches 90 to 100 degrees F I must remind you here of the fact, that the higher the temperature of the air, the more water it can absorb, and that for example, 90 degrees relative humidity at 90 degrees F is vastly more than 90 per cent relative humidity at 32 degrees F And now imagine people who lived here through the summer months and inhaled that terribly suffocating moist air, having to breathe in winter an atmosphere which contains hardly any moisture "*Les extrêmes se touchent*" in nature as well as in real life Next to the multi-millionaire, who has so much that he does not know how to consume his interests, goes the poor man whose children are starving for want of bread Next to a summer with more than superfluous moisture, we have to stand a winter with much too little of it After inhaling an air with 90 per cent relative humidity we are forced, through the incompleteness of our furnaces, to inhale day and night, an air with mostly below 30 per cent relative humidity Feb 5, 6 and 7, 1895, when the outer temperature was about zero, the hygrometer in my office sank to 15 per cent

And now comes the important question What influence has this abnormally dry air on the upper respiratory organs in general, and on the retro pharynx especially? In his above cited book, Billings says "The precise influence which either the absolute or the relative amount of moisture in air has upon health is uncertain, for habit enables man to undergo great variations in this respect without marked ill effect" While I agree perfectly with this last sentence, as otherwise we would have no healthy person in New York, I am opposed to his idea that simple dryness of the air is not injurious to health To prove this statement, he cites Fort Yuma, Southern California, where during April, May and June the average temperature day and night is 90 degrees, even 100 degrees F, and no rain falls Yet there is no additional sickness He forgets two things 1, that the people in Fort Yuma, live almost permanently in the open air, which is never stationary, and 2, that in spite of this great heat and lack of rain, the moisture never sinks to 20 or 10 degrees relative humidity When Billings says "A dry air with a uniform temperature makes a healthy climate as in New Mexico," he is perfectly right, but this dryness does not mean 10 to 20 per cent relative humidity, but 50 to 60 per cent

I must say the same about similar ideas of Hermann Reinhard (Dresden)[4] He tells us that travelers feel comfortable in some parts of the desert of Sahara, in spite of a comparatively high temperature, as the "air is very dry" and perspiration can take place But we can conjecture what *he* calls dry air, as he indorses the recommendation of some German and English physicians, as to certain places of Cape Land as health resorts on account of their dryness And in examining this nearer, we find that the average relative humidity here, is for October, 42 per cent, for June 62 per cent and for the year 51 per cent ! I would not hesitate for a moment to recommend such places myself, but you understand the great difference

Of late, very little has been written on this subject of heating, and among those authors on this part of hygiene, who discussed it some years ago there is a great dissension of opinion The majority of them, almost all Germans, are in favor of hot air heating, as I think for want of knowledge regarding the way heating is done in this country So Hermann Fischer (Hanover)[5] considers our hot air heating as the best, and attributes most of its disagreeable effects to uncleanliness A similar view is held by von Fodor (Buda Pesth) who attributes[6] the ill effects mostly to the combustion of small particles of air and the products of distillation, that are developed on the hot surface of the furnace

These arguments in favor of hot air are based chiefly on the fact observed by von Pettenkofer, that in the royal castle in Munich, the air in the rooms, *i e*, after coming from the air tubes, contained more humidity than before If we do not believe in wonders we must accept that there was some sort of humidity developed in the rooms themselves This is the only solution I can offer for this single fact, that is in contrast to all our experience The ideas of H Reinhard are based mostly on theoretical deductions The practical investigations he had made in the Kingdom of Saxony, were done by the teachers who, as a rule, do not understand anything about such things Beside these investigations were continued during one week only, and the influence of wind, outer temperature, etc, is hereby such an important factor and underlies such great accidental changes, that we can not take these investigations as confirmatory

On the other hand, there are men like Wolffhugel, Erismann and Krieger who say that the use of hot air heating is to be deprecated They consider it deleterious and make the dryness of such rooms responsible for the disposition to catarrhs of the upper air passages, croup and diphtheria (sic!) etc

The man whose views come nearest to mine is Theod Deneke[7] It is well known that the air has the capacity of absorbing moisture from bodies which lose it by evaporation As, through evaporation, heat is generated, it takes up the heat also The dry air therefore, has the dual property of drying and cooling To what degree this takes place depends upon the dryness, the temperature of the air, and the rapidity of its motion The dryer, the warmer and the more movable the air is, the more thirsty it will be for humidity Now the absolute quantity of the water given off from the whole body is of no hygienic consequence, as it can be replaced constantly by the supply of fresh water There is a difference, however, with some sensitive parts of the skin and mucosa "It is likely," says Deneke, (loc cit), "that when locally the amount of the water evaporation is much augmented, the supply of the water lost toward the surface can not go on quick enough, and as a consequence of this, pathologic changes of these parts may result The portions of the body thus situated are the superficial mucous membranes, which, on the one hand, are constantly exposed to the external air, and on the other from direct communication with the respiratory passages" This is very rational Epidermis and epithelium also here generally protect against the too rapid drying process, but in spite of this it will happen that a suddenly augmented or continuous evaporation will take more water from the superficial layers than can follow from the deeper portions The consequence will be a drying up of the surface and a loss of the elasticity

[6] Ibidem p 118

[7] Ueber die Bestimmung der Luftfeuchtigkeit zu hygienischen Zwecken Ztschr f Hygiene I, p 4[illegible]

And now we come back to our first experiments and will recognize their importance in this regard We have seen that when we connected the Liebig apparatus with the nose, and allowed the perfectly dry air to pass through, this was saturated with humidity after it had passed through the nose It would naturally make only a slight difference whether the air is perfectly dry, as in the Liebig apparatus, or whether it contains 20 or 30 degrees of humidity, as so often found in our residences The difference is only in degree It is, however, proved that dry air if inhaled will become saturated in the nose and naso-pharynx, that is to say, the dryer the air is we inhale, the more moisture will be given off by the nose and naso-pharynx The work of the nose and naso-pharynx will be so much greater with every particle of air we inhale How long the mucous membrane of these parts will be able to furnish the necessary water supply, will only therefore be a question of time Consequently, we will, sooner or later, reach that point where the mucous membranes of these parts will be dry like a well in summer This will occur, for example, in very cold weather only temporarily in perfectly healthy persons, or permanently as we see it in so many thousands of times in pathologic conditions

Now the manner by which this leads to the development of a post-nasal catarrh is not so simple Supposing we have a person with a normal nasal mucosa If dry air is inhaled for any length of time by this person, to such a degree that no more water can follow from other parts of the body, the erectile tissue will respond to this irritation like any other irritation, with swelling, which will recede as soon as the irritating cause ceases When, however, this has lasted for a longer time, the swelling remains in spite of good hygienic conditions and the result is impeded nose breathing or mouth breathing

Under such conditions the secretion that continually comes from the mucous glands of the naso-pharynx has no work to accomplish The air does not pass the retro-pharynx and the watery discharge dries out while the solid substances, which normally are carried away with respiration and lubrication, stagnate at the retro-pharynx The *secretion* under this drying surface is *less than normal*, as very soon solid masses adhere to the mucosa, and prevent the escape of the glandular secretions Especially if venous stasis occurs, as it often does, blood and lymph extravasations take place, microorganisms develop on this albuminous soil and the catarrh of the mucosa results

This, in my estimation, is by far the most frequent way a post-nasal catarrh is developed I will add only that, as far as I know, Bosworth was the first who claimed a diminution of the secretion in this disease, although for different reasons than mine That such people discharge more than others proves nothing The dried masses lying in the post-nasal space are foreign bodies which the unfortunate possessor tries to get rid of by hawking, coughing, blowing or the like This only increases the glandular secretion of the neighboring parts, i e, of the nose, the lower pharynx and mouth It seems to me, that the so-called granular and lateral pharyngitis and the hypertrophy of the tonsil of the tongue are nothing less than a consequence of this condition So we can say we have an increased discharge of phlegm *through* a retropharyngeal catarrh, but *not coming* from the retro-pharynx

Another way for the development of such a catarrh is the following if the mucous membrane of the nose is already atrophic, or it has been cauterized to such a degree that the erectile tissue can not respond to every insult, or if it can, not for a long time, then it will happen that we can not breathe through the nose, although the passages for the air are wide enough, often only too wide This will occur, whether scabs and crusts are in the nose or not When the nasal mucosa is dried out by the dryness of our houses, then by inhaling only through the nose we have not the sensation as if our hunger for air is stilled The air after passing the dry nasal mucosa produces a disagreeable, not natural sensation in the retro pharynx The consequence will be that we expel it right away and breathe through the mouth

I do not know whether you ever had that sensation, that you could not breathe through the nose, although its passages were free enough In such a case the nostrils are extremely dry and your hunger for fresh air does not seem to be satisfied You are in a state of apnœa The air before reaching the retro-pharynx must be partly saturated with moisture and if it is not, it seems that it can not be tolerated, and only irritates this part Instinctively we give up nose breathing and breathe only through the mouth If scabs or crusts prevent nose breathing, this will naturally happen sooner As soon as this takes place, the catarrh of the retro-pharynx will develop in the same way as before

I took the swelling of the nasal mucosa as an example only for obstructions of the nose Anything else that obstructs nasal respiration as polypi, etc, will naturally have the same effect The fact is, that any atmosphere containing less than 40 per cent, of humidity will have the same effect if a person is subjected to it for a longer time, and this we all are, more or less, during at least five months of the year Although the human body can live under many unsanitary conditions, still we must not forget that a certain amount of moisture in the air is necessary for respiration, as well as for transpiration

A heated room should not be warmer than 65 degrees F If we then feel cool, it is a sign that there is not enough moisture in the air, in other words that the air not only absorbs from the upper respiratory tract, but from our lungs also humidity, and with that heat As soon as the hygrometer in a room with 65 degrees F shows 50 to 60 per cent relative humidity, this will be rather too warm, than too cold But this never occurs in our houses during winter time

On the contrary, the people feeling cool at a temperature of 70 degrees F have extra fires made, and bring the temperature to 80 degrees F and above, as I have not infrequently seen it If they try to go out into the open air, where a humidity of 80 to 90 per cent encounters them, these extremes must have a very bad effect on the whole system, and "colds" on every *locus minoris resistentiae* will be of general occurrence The principal reason why so many people like a Russian bath in winter, is that they are only too glad to fill their whole respiratory tract with moisture This relieves them greatly of the dryness in their system

I will add here that I always noticed more patients complained of dryness of the throat and nose after a cold spell But during the last winter, 1894-95, which was a very cold one, the number of patients at the Montefiore Home who complained of this was immense It was entirely out of proportion to the few patients whom I see at the above institution in summer, when they are in the open air during the greater part of the day

The answer how to prevent the bad effects of our poor heating system, will be, not only do we need in building a house a mason and a builder, a carpenter and a so-called sanitary plumber, but also a man who, from a medical standpoint, could judge whether the heating system and other things are sanitary or not But so long as we do not have such officers, we have to see to it ourselves that the furnaces are correctly built, that is, not too small, etc, and that a provision for the supply of moisture be attached to the furnace

This latter is, so far, very hard to fulfill I have written to different furnace-makers but all the appliances for this purpose which I have tried were not satisfactory It is my conviction, however, that ere long this will be improved if only the attention of the physicians and the public is drawn to it

The next point that comes into consideration in connection with our subject are the so-called colds As natural and well founded as it may be to try to prevent colds, so ridiculous and in its sequelæ so dangerous is the fear of catching cold, that it terrorizes in this country all classes of the population You can justly say, that never had the people such nonsensical, hare-brained ideas regarding the hygiene of their bodies as at the end of the enlightened nineteenth century, when everybody thinks they understand a good deal about medicine Through advertisements of patent medicines, indorsed not unfrequently by prominent ministers, through unscrupulous newspapers presenting unripe medical ideas to the Sunday table of their public, they learn just enough to make everything wrong The manner in which we dress ourselves, how we live, when we go out, or stay at home, etc, in everything is governed by one idea, the ghost of catching cold Although it may be that many people frequently catch cold in the open air, this should not be a reason for us to seclude ourselves from it On the contrary, we should just go out in the open air, as these people become ill just because they do not get enough fresh air The animal organism is destined to breathe permanently in the open pure air, and every hour that we sojourn in closed rooms is detrimental to the organism Naturally I will not say by this, that we should give up our homes, our culture, etc, and become cave dwellers, troglodytes or, like the old Germans, sleep in the woods on bear skins, by no means Only one thing I should like to impress upon the public, that we should extend our cultural endeavors also to the care and proper development of our respiratory organs Let us stop for one moment to consider how many hours the average person in New York is in the open air, and we shall soon see that we do a great deal for our digestive, but nothing for our respiratory organs In the morning one walks for a few minutes to the nearest station or car, rides down town in a vehicle overcrowded with humanity, and filled with the most miserable atmosphere, only to remain an entire day in an office, or more frequently still, in a factory loaded with dust, smoke and all possible foul gases, a factory that is never reached by any fresh air draught Evenings one returns homeward in the same manner, to go afterward into an overcrowded theater or the like

And the women? Well, the poorer ones work in a cigar factory or in a sweat-shop, packed together in a room, the air of which would even be too bad for the worst criminal The well-to do women are better off in some respects, but with them the fear of catching cold is so paramount that they do not dare to go out when the wind blows a little bit stronger, or even if it should rain a trifle In accordance with these ideas the children also are brought up One does not risk sending them out, without being convinced beforehand that no rain or snow is likely to fall If, however, they are once caught in a shower, or the like, then naturally such a child has a cold, and one reproaches one's self for having been so careless I can not restrain myself from reminding you of the words of an old physician, Johann August Unzer, who wrote as follows "Nature has given to the man the open air as the element wherein he should live Nevertheless we have been too politic, that we should not have noticed that this element is soon too cold or too warm, soon too moist or too dry, soon too windy or too quiet We take care that our children, who are born to breathe fresh air, do not come in contact as long as possible with it We consider it a matter of conscience to take them on a beautiful day, out of the stinking room into the open air, that by no means they should get too early a better air than that infected with the smother of effluvium, with the smell of the swaddling clothes, food, coal and foul vapors Yes! in order not to lose any of these precious odors, we plaster up the windows and cover up the doors We grown up people so little lay aside the prejudice of our wet-nurses and parents against the free air, that we prefer to look at it as the cause of most diseases And when we, finally, through this pernicious smartness have acquired bad diseases, we lock ourselves up in a still much worse air, nail our windows and wish that our servants were ghosts who could come through locked up doors, only that we should not need to suffer a little restoration by opening them So peculiar are people, when they become too smart for Nature!"

So far, Unzer, whose words are more applicable today than formerly

If we want to cure a post-nasal or similar catarrh of the respiratory organs, it is not sufficient to prescribe a gargle or a spray, we must treat the whole body, as every cold, every noxiousness of the skin works back on the mucous membranes

Our whole mode of living is apt to make us susceptible to the influence of weather, and therefore we must fight against it, we must harden our body, not to get a coryza or bronchitis from every so beneficial breath of air. We must move daily for a certain time, not too short, in the open air, and especially should we spend our vacation, our pleasures in the open air. If you send your young people, suffering from any chronic trouble of the respiratory organs to the mountains, you will find them only too often in an overcrowded ballroom, dancing all night. How much better would it be for them, to do this in the open air! When shall we see the day, that our children are no more taught in overcrowded prison like school rooms, but, as it is the highest of my ideals, in a garden under the trees? To have a school for hundreds of children, without even an open place to play in, as the custom is now in public and private schools, is a crime against the rising generation.

Another prejudice that prevails here more than elsewhere, is that one should go out little, or not at all in rainy weather. The old story goes, that one gets wet feet from it, and that is detrimental. But why this should be more detrimental than wet or cold hands, no one can as yet explain to me. The young plant needs rain for its life, and should we deprive our children of the same element, that acts so refreshing and vivifying upon them? Is it not unheard of, that school children are not allowed to go home at the noon hour when a few drops of rain fall from heaven? And is it not a shame that a school commission, unassisted by physicians, has made this a law?

Not long ago, Dr. F. Welz made investigations in the hygienic laboratory in Freiburg upon the contents of bacteria in the air. He showed that an increase of bacteria takes place toward the warmer season, a *decrease* in *winter* and *in rainy weather*. So from this side also, rain is considered favorable and healthy. You most likely have heard of the great "curer" Kneipp. How is it that this Bavarian priest, an honest, as I believe, but absolutely ignorant peasant, has such great success? If you come to his village, Worishofen, you will find all the patients badly clothed and their feet bare. The women wear no corsets, the men no underwear. "All or nearly all of them," says the *Normandie Medicale*, (quoted from the *New York Medical Journal*, Sept. 1, 1894), "have faith in the priest. This faith is evidently a great aid to the treatment, but it is incontestable that there is something in the priest's mode of treatment. This does not consist alone in applications of water; a number of medicinal herbs are employed, plenty of air, and a hygiene altogether different from that usually practiced. Very little clothing is worn, linen trousers, a coarse linen skirt, no underskirt, a jacket, a straw hat, and sandals, but no stockings, compose the usual costume. In this manner cutaneous respiration is facilitated as much as possible."

Our knowledge is to a great extent an empirical one, and we as physicians, have accepted lessons from wherever they came. So we have for example, the wet packs from a shepherd, Priessnitz, in Silesia, we have the much-used drug, cascara sagrada, from the Indians, and now do not let us be blind against everything that this peasant Kneipp teaches us. It is the cutaneous respiration that is systematically suppressed by our mode of dressing. This system of over-dressing is a total failure, as the diseases of the respiratory organs were never so numerous as in our generation. Away with this system that has made 80 per cent. of our population nothing but pathologic specimens! If Mr. Kneipp recommends us to go barefoot, this is only part of a system to harden ourselves, which we all know, but which we never follow.

Those country people, in Germany and elsewhere, are really lucky who go barefoot in summer, and thus not only harden their feet, but their whole system, especially their respiratory organs. Among such people you will seldom find rheumatism or catarrh. You can all do the same, even if it were only for a few minutes in your room. Even that helps. Before all, you should see that your children should go barefooted whenever they are at home. If they do it in summer in the country, so much stronger will they be, and so much less "catarrh" will they have in winter. Somebody told me that it is the style at the University of Oxford for the children of the professors to go barefooted until their twelfth year. Those children are said to be exceptionally healthy.

In this connection, says the celebrated physiologist Brucke: "I can not approve of the fact, that in some schools the children are forbidden to come barefooted. This is a gratuitous and unnecessary taxation of the parents. By his nude feet, the child injures neither the teacher nor the other scholars, but he does so very much by feet dressed with shoes, but not with clean stockings."

The celebrated African traveler, Rohlfs, tells how he visited a wild tribe whose chieftain was suffering from a terrible coryza. He was the only one who had this affection, and he was the only one who wore shoes and stockings!

That cold baths and washings are excellent means of hardening ourselves is generally known. If anybody should demur and say that the peasants as a rule bathe very little, and still are much healthier than city people, he forgets that the life of a peasant consists in perpetual hardening, and that he does not need these means. If anybody should believe that he keeps his body healthy by wearing underwear winter and summer, he is very much mistaken. Underwear is to be recommended only in very cold weather, otherwise it is injurious to one's health. The more clothes we have on, the more sickly we will be, and the less clothes the healthier. But the most objectionable of all, are rubber shoes and rubber boots, in which our feet roast as in an oven. The climate has nothing at all to do with this, and just because a change of weather occurs so very frequently here, we must protect ourselves against it in a natural manner, *i. e.*, still more harden here than elsewhere. I again quote from Brucke, who says: "The reason why Italians of the higher and middle classes are effeminate, is because the fashion compels them to go about even in the hot summer, chiefly in dark woolen clothing, under which they generally wear chemises."

If one compares this garb with that of the old Romans, one will very soon answer the question, whether the effeminacy comes from the climate or from the garb. So it is in this country, but I will abstain from drawing any comparison between the wild Indian and the hypercultured young American of to-day.

In conclusion, I quote from Shelley:

"   but in this life
Of error ignorance and strife
Where nothing is, but all things seem,
And we the shadows of the dream,

It is a modest creed, and yet
Pleasant if one considers it
To own that death itself must be
Like all the rest a mockery '

943 Madison Avenue

DISCUSSION

Dr Casselberry—Over heated apartments and too heavy clothing are certainly conducive to ' taking cold " I am of opinion that more persons "catch cold" by getting too hot, than by being too cold Neither is it necessary to become chilled while in an over heated condition in order to suffer that congestion of the mucous surfaces termed a "cold," although this doubtless is one of the methods, but the mere relaxing effect of heat to the body surface is capable of congesting at least the turbinated bodies and starting a cold This is especially true of over heated rooms With our present modes of heating I think 65 degrees scarcely sufficient, but 70 degrees F is adequate

I would advise against the wearing of very heavy underwear, preferring a light grade of woolen underwear for winter, supplemented by varying grades of outer clothing and overcoats For spring and fall, still lighter underwear of good merino or wool, and for midsummer, gauze for the ordinarily robust individual The daily morning cold bath invigorates the vasomotor system and so prevents more certainly than any other one thing frequent "colds" It and other hygienic management should supplement local treatment in catarrhal cases I am not in accord with the author of the paper regarding the evil effect of overshoes Ordinary leather will not keep out moisture, and wet or even damp feet in cold weather endured for hours without opportunity to change, is a prolific cause of "cold" A protective overshoe as low as will answer the purpose and removed on passing in doors seems necessary

Dr L R Ryan, of Galesburg, Ill —I did not hear the whole paper, but there are some points that are of vast importance, and one which should be brought to the attention of the people at large, and that is the matter of excessive clothing, and living too much in confined houses In this connection, an article I recently read in a current magazine comes to my mind It is in regard to the condition of the Tierra del Fuegans of South America, they were naturally a strong robust people, lived outdoors continually and wore little or no clothing and in their natural condition were free from disease When the missionaries established headquarters there and converted them to Christianity, inducing them to wear clothing and live in civilized houses and in a civilized manner, they immediately began to deteriorate physically, until the whole tribe has been destroyed by throat and lung diseases and especially consumption We must keep as closely as possible to nature and avoid those unnatural changes

Dr Woolen—If, as the gentleman claims, that in his State the children have colds, etc, in spite of their being out-of-doors all the time, there must be other reasons for the development of such catarrhs which I do not know, but I would certainly not blame the fresh air for it Regarding the Doctor's remarks about the seat of the polypi I must say that there are a great many seated much higher than the middle turbinated

CANCER OF THE RECTUM—ITS EXCISION AFTER THE METHOD OF KRASKE AND MODIFICATIONS THEREOF, WITH A REPORT OF CASES

Read at the twenty fifth Annual Meeting of the Medical Society of the State of Colorado June 18 1895

BY CHARLES A POWERS, M D

CONSULTING SURGEON TO ST LUKE S HOSPITAL AND ATTENDING SURGEON
TO ST ANTHONY S HOSPITAL LATE ATTENDING SURGEON
TO ST LUKE S HOSPITAL AND TO THE CANCER
HOSPITAL NEW YORK

DENVER COLO

The old methods of excising the rectum have been in large part superseded by the sacral procedure, and it is safe to assert that of all malignant growths affecting this part of the body, but a small proportion will be found amenable to cure when dealt with from the perineum

Although Kocher, of Berne, had for some years added to the posterior incision a removal of the coccyx, it remained for Kraske, of Freiburg, to lay down those fundamental rules which, though since modified from time to time, enable us to cope with something like an assurance of success with this distressing affection

It was before the German Surgical Congress of 1885 that Kraske first proposed to gain easy access to the upper portion of the rectum by resection of the lower part of the sacrum This original procedure has since undergone important modifications Its essential details are as follows the patient lies on the right side somewhat in the Sims' position, the thighs and legs flexed and a stout support raising the pelvis A cut is made from the left border of the sacrum, opposite its second vertebra, to the anus, this cut quickly curves to the midline at its upper end and reaches the posterior surface of the sacrum and coccyx The coccyx is removed, the left lateral sacral ligaments severed, and the sacrum chiseled across obliquely from a point opposite its third foramen on the left side to the lower right hand corner The severed piece is removed and the bleeding checked The tissues are divided in the midline until the posterior surface of the rectum is reached The anus is freed and the rectum loosened, chiefly by blunt dissection from below upward, to a point well above the growth The peritoneum is opened, the rectum drawn down, cut off, the remaining end brought out below the cut surface of the sacrum and stitched to the adjoining skin

The peritoneal pouch is occluded by a plug of iodoform gauze and the entire open wound filled with the same Healing takes place by granulation and a sacral anus results

Valuable as was this procedure in the efficacy with which a high lying cancer could be reached, it left much to be desired and various improvements in technique were set forth as different operators gained experience Schede, instead of plugging the peritoneal pouch sewed it up as soon as the rectum had been drawn down and before it had been severed, and when the anus was not involved he united the cut end of the rectum to it, thus restoring the continuity of the canal and giving the control of a sphincter In practice it was found that the passage of feces tore out the stitches, prevented union, and a fecal fistula generally resulted To obviate this, Schede did an inguinal colotomy at the time of or directly after the operation This not only added to the time occupied by the serious major procedure, but left the lower bowel filled, and has now been superseded by the colotomy being done so long prior to the proctectomy as to allow of firm fixation of the gut in the inguinal region and a fairly thorough cleansing of the rectum itself This preliminary colotomy may be considered indispensable whenever it is desired to preserve the sphincter ani and do an immediate anastomosis

With a view to avoiding the loss of the resected bone and the consequent weakening of the pelvic floor, Levy, in 1889, devised an osteoplastic procedure whereby a flap of bone, together with the overlying soft parts, is turned up and replaced He made a transverse cut, some four inches long, across the sacrum at its lower end Lateral cuts are made from the ends of this through the gluteus maximus muscle, the anterior and posterior sacro-sciatic ligaments are divided, the bone chiseled across, and with an elevator the connective tissue on the anterior surface of the sacrum is separated The skin flap with the attached bone is then turned down and the rectum comes into view This is resected, the cut ends united, the bone flap replaced and sutured, the horizontal incision closed, the lateral ones united in part and well drained While this is, in theory, a suitable procedure, it is in fact difficult to perform and unsatisfactory in results, and it remained for Rehn and Rydygier to devise a procedure which seems thus far to give the greatest promise In this, an incision is made from the posterior inferior spine of the ilium to a point midway between the anus and the coccyx This is met by a transverse cut across the sacrum at the point at which it is intended to divide that bone The left sacral ligaments are divided, the bone cut across, the bone flap turned over to the right side, the rectum excised and sutured in the usual manner and the bone flap returned and sewed in place Gauze drainage is provided and the skin wound closed in part

Exfoliation of the bone rarely occurs, and even though this should take place, nothing will have been lost by the attempt at osseous repair The results in typical cases are all that can be desired, so far as concerns the immediate condition The retained sphincter insures the nearest approach to a normal bowel condition and the pelvic floor is left intact In those cases in which the anus is involved it is needless to say that this is impracticable Here the gut must be fastened to the skin In many cases, control of feces and gas will be improved by twisting the lower end of the rectum as advised by Gersuny In every case the inguinal anus should be closed in the usual manner so soon as the rectal condition may warrant

Whatever the procedure employed, sacral resection of the rectum can but be considered as belonging to the severer operations in surgery It may be easy or difficult to perform When the growth is small and the tissues about the rectum free from infiltration, a blunt dissection may be made with the loss of but little blood If, however, the perirectal tissue be involved, a wide dissection must be carried out and the operation may be long and bloody Oozing from the cut surface of the sacrum can be checked by gauze tamponade, all bleeding vessels must be quickly caught and tied At all times intelligent retraction and active assistance are of the greatest value It is all important that the loss of blood be the least possible, hemorrhage being the greatest factor in the production of shock

In nearly every instance the peritoneum must be opened, to allow a drawing down of the gut This adds but little to the danger of the procedure, an immediate suture can quickly be made The sigmoid flexure must be detached from the surface of the sacrum to allow a drawing down of the upper segment

In cases in which four inches or more of the rectum have been resected, it is necessary to loosen it very thoroughly from the sacrum in order to approximate the cut ends without traction This loosening is accomplished in part by dividing the mesentery, and in part by blunt stripping up It is not infrequently necessary to ligate the superior hemorrhoidal artery on either side, and in such cases Kammerer has proposed to cut away still more of the rectum and bring down a portion better supplied by other branches of the inferior mesenteric, in order to do away with the possibility of an anemic necrosis of the lower end of the gut The approximation must be made without tension, for the blood supply is poor at best, and the bowel is without the peritoneal investment which is so great a factor in prompt healing In those cases, however, in which there is no tension, good blood supply and a diversion of the feces through a previously made inguinal anus, primary union will be found the rule rather than the exception

In certain cases the surgeon will find it necessary to content himself with a partial operation and to postpone completion until a subsequent sitting So, when the amount of blood lost has been considerable and the shock severe, as in patients who presented a previously weakened condition, one may be obliged to hastily tack the bowel posteriorly, plug the peritoneal opening and tampon the entire wound The operation is a severe one, frequently bloody and tedious The writer fails to understand Bardenheuer's assertion that he completes the procedure in fifteen or twenty minutes, stripping up the rectum by blunt dissection and often finding it unnecessary to open the peritoneal cavity If amputation be made and a sacral anus established it may be possible to avoid opening the peritoneum Rarely can this be done, however, when the bowel ends are united

While the mortality attending this operation has steadily diminished, it is yet considerable From the data at hand, I judge it to be in the hands of competent operators, about 20 per cent The chief causes of death are shock, hemorrhage and exhaustion, peritonitis, I believe to occur but seldom, and sepsis should be infrequent Drainage is easily made and should be liberal A caution may be made regarding the too free use of iodoform gauze, the surface left is large and quickly absorbs I have myself seen iodoform intoxication, very quickly disappearing, however, on removing the drug

My own operations have been three in number In one additional late case I removed the sacrum, but found the disease too far advanced to warrant attempt at excision I should have done better had I followed this course in my first case which was the fatal one In a considerable number of instances I have advised against radical operation, in place, thereof, a palliative colotomy

My cases are as follows

Case 1—Cancer of rectum, Kraske's operation Death from acute anemia and shock Miss K, age 27 years, single, was transferred to my service at St Luke's Hospital New York, July 25, 1893, by my colleague, Dr Robert Ab who was about leaving town for the summer No previous history bearing on the present condition Three months before seen she had begun to suffer with obstinate constipation from which she had previously been free Fecal movements were narrow and painful, but not bloody The patient had lost thirty pounds in weight, and much strength during the three months, her general condition was fairly good Pulse 86, temperature 99

The examining finger introduced into the rectum revealed an annular, irregularly nodular mass extending three inches above the anus The constriction admitted the tip of the index finger, which could be swept about, over and around the tumor On vaginal examination the mass was felt to push the posterior vaginal wall forward, but not to involve it The lymphatics in the immediate neighborhood were enlarged

Eight days were occupied in putting the patient in the best possible condition, and on August 3 the following operation was made ether, six inch incision over sacrum and coccyx to anus, coccyx and lower segment sacrum removed (Kraske) Anus and lower part of the rectum freed from surrounding tissues Dissection difficult and bloody, owing to fairly extensive perirectal infiltration Cancerous mass found to extend well up anteriorly Peritoneum opened, mesorectum severed rectum drawn down and cut off stump brought out beneath cut surface of sacrum and sutured to skin Peritoneal opening plugged with iodoform gauze, wound filled with boro-salicylic gauze The operation lasted two hours and the patient lost a considerable amount of blood Vessels were clamped as soon as seen, but there was a continuous general oozing which could only be controlled by pressure At the close of the operation the pulse ran from 140 to 160 An infusion of salt solution reduced it to 120, in spite, however, of active stimulation and further infusion the patient sank progressively and died thirty six hours after the operation A microscopic examination of the tumor showed it to be carcinoma

I am now convinced that this growth was too extensive for removal This was not understood until the rectum was exposed I should have done better had I contented myself with a proctotomy above the tumor, or, better, done an inguinal colotomy at a subsequent time In this connection the following may be of interest

Case 2—Mrs D, a woman of about 40 years was referred to my service at the New York Cancer Hospital Oct 1, 1893, by colleague Dr H C Coe For six months she had suffered with painful bloody stools, steadily diminishing in size Examination revealed a nodular mass encircling the rectum about two inches above the anus The finger passed through this High infiltration was not felt per vaginam October 11 Kraske's operation On opening the peritoneum, the infiltration was felt to extend too high to warrant attempt at removal Peritoneum closed and wound packed The patient made a smooth convalescence and was advised to have an inguinal colotomy made whenever the symptoms should demand it In April, 1894, she was in good general condition I have not heard from her since

Case 3—Cancer of the rectum Kraske's operation Recovery *Freedom from relapse at the end of twenty months* Mrs F, aged 35 years, was referred to my service at the Cancer Hospital Sept 28, 1893, by Dr F A Manning For six months she had observed mucus and bloody discharge with rectal pain The stools had diminished in size, on examination a hard nodular mass was found to encircle and constrict the gut just above the anus Operation Oct 9, 1893, sacral resection Peritoneum opened, mass found to extend one inch above the rectoperitoneal margin and to involve the anus Rectum amputated above growth and upper end fixed beneath sacrum Wound packed with iodoform gauze Slight iodoform intoxication which disappeared on change of dressing Undisturbed convalescence The patient regained good control of feces but not of gas I learned of her recently She has had no evidence of recurrence Pathologist's report "carcinoma"

Operation was in this instance easy The growth was confined to the rectal wall and anus The loss of blood was but slight I do not think we can determine definitely the extent of the disease prior to exploration We can not make sure in an individual case that the operation will be accomplished rapidly and easily We must in all instances be prepared for a long and difficult procedure

Case 4—S M, a man of 52 years was admitted to my service at the Cancer Hospital June 15 1892, with a history of having had occasional bloody stools for three years, these having of late become painful Examination revealed a tender, bleeding, granulating tumor just above the anus, through which the fingers could be passed The anus did not seem to be involved Operation June 30, 1892, in my absence by Dr Van Arsdale, assistant surgeon Sacral resection, six inches of rectum removed, end of gut drawn down and stitched posteriorly to anus Wound packed, smooth healing On July 18 and again on August 21 secondary operations were done to restore the continuity of the gut This was effected and the patient left the hospital completely healed and with control of feces, though not of gas Pathologist's report "carcinoma"

Case 5—Cancer of rectum—Resection—Recovery Mrs R a woman of 39 years, came to my office in February, 1894, with a history of painful defecation during the past four months She had occasionally noticed blood in the stools and had recently felt a lump" Examination revealed a rough annular, friable mass just within the anus and lying rather on the anterior rectal wall On vaginal examination it seemed limited to the lower part of the rectum Operation, sacral resection, peritoneum opened and gut pulled down A string of infiltration ran well up on the anterior wall After removal of some five inches of the rectum, sparing the anus, the tension was so considerable that in view of the patient's general condition it was deemed unwise to prolong the operation by a high loosening of the gut It was accordingly brought out beneath the sacrum Undisturbed convalescence Pathologists report "carcinoma" I am unable to ascertain the present condition in this case

All of these operations were made before I became familiar with the osteoplastic procedure of Rydygier In a future suitable instance, I should proceed, so far as present knowledge goes, after his plan It permits of the most thorough extirpation possible with restoration of the bony parts

Much depends on a proper selection of cases A large proportion of patients with cancer of the rectum will be found, when first seen by the surgeon, to be in too advanced a condition to warrant thought of cure The disease progresses slowly and often reaches an advanced stage before the increasing occlusion of the gut seriously calls the patient's attention

The earliest possible diagnosis on the part of the family physician is of the greatest importance These cases first come under the care of the general practitioner, and his examination should be most thorough In no affection about the rectum should digital examination be omitted The examining finger is of far greater value than instruments, so far as the region which lies within its reach is concerned In case of a suspicious though indefinite ulceration, dilatation of the sphincter with removal of a small piece of the tumor for microscopic examination will be found of the greatest service So long as the patient's condition warrants, we are not justified in leaving any measures undone which may aid in establishing a positive diagnosis I have more than once called attention to the fact that age is of slight value in differentiating cancer The age of the patient in Case 1 was 27 years Cancer is not so very infrequent in patients under 30 years

It is difficult to obtain the exact mortality attending extirpation of the rectum, in general, it may be estimated at about 20 per cent Before the introduction of the Kraske method, it was something like 50 per cent It will doubtless fall materially as the selection of cases and the operator's technique further improve

Curtis collected statistics of 420 cases from 11 clinics and found that without separating the perineal from the sacral operation, the mortality was 15 5 per cent It is without doubt greater in the sacral than in the perineal, as in the former the disease requiring operation is further advanced and the procedure itself is much more severe

As regards the chief point in any operation for malignant disease, immunity from relapse, I am unable, with the literature at my command to give even approximate figures Curtis, in 144 cases which had run over four years, found 21 5 per cent of four year cures These were, however, both sacral and perineal operations, and more of the latter than of the former Whatever the percentage of radical cures may be, it is sufficient to encourage surgeons in their attempt So far as we now know, the only hope of cure in cancer lies in its early recognition and prompt and wide excision, and it is on these lines that progress must and will be made Advance in the past ten years has been steady and much ground has been gained It is to be hoped that the future will give us a specific, be it in the line of serum or other therapy, against this most malign disease At present, however, our trust must be placed in operative procedure, and in the accomplishment of lasting results the physician and the surgeon must cooperate

Stedman Block

WHAT CAN AND CAN NOT BE DONE FOR NASAL CATARRH BY LOCAL APPLICATIONS

BY ALLEN DEVILBISS, M D
TOLEDO OHIO

The fact that the majority of humanity are afflicted with some form of nasal disease, and after doing all we can by hygiene, internal medication, and if necessary the removal of tissue, there will in most cases remain a condition requiring local applications, are sufficient reasons for our trying to suggest a plan whereby the remedy used may be applied so as to produce the best results

A spray thrown into the anterior part of the nose with its direction parallel with its floor, can not be expected to produce a cure or relief, on account (as a rule) that the diseased condition is located in the roof and not the floor, neither can we expect to accomplish good results by inhaling through the nose a vapor only to come in contact with the mucous covering the membrane

To do effective work, the instrument should be so constructed that its point may be carried into the vestibule far enough to reach the nasal cavity proper, and the spray directed toward its roof so that the mucus will be washed away by the solution used This can not be accomplished by the counter current from an atomizer or the vapor from a vaporizer

To meet this want I devised an instrument with a movable spray-carrying point which may be set so that all parts can be treated by a direct current, it may be used for spraying any remedy that will be beneficial to an inflamed mucous membrane, or that will not injure a healthy one It has no leather or rubber washer, consequently can be made perfectly clean by boiling Solutions can be easily warmed by holding it over a gas jet or lamp a few moments, and this is essential, for by applying them warm there is no shock, and it soothes the membrane, which it will not do if applied cold

When using oils keep the point below the level of the cup, as you will then have the advantage of gravity to bring it from the cup to the point ready for atomization In this way the oil is carried to the membrane with as little air as possible

When treating the patient anteriorly, set the point upward to throw in the direction shown by No 3, Fig 1 Place the left index finger beneath and near the movable point, carry it into the nose, resting the finger upon the upper lip, raise the cup above the level of the nose, give two or three compressions of the bulb, and the roof of the nose will be flooded with the remedy By using it in this way there is no danger of irritating the membrane by continually pumping air against its surface, the air current being a necessity as a carrier and in every other way a disadvantage

Treatment in a majority of the cases given in this way will be all that is required, but in some cases it will be necessary to reach the posterior turbinate bodies and meatuses by throwing a spray from behind the soft palate This can be accomplished best by having the patient hold down his own tongue, for by so doing the parts will remain passive, which must be to make a perfect application, fill the cup part full of the solution to be used, heat over a lamp or gas jet, set the point anteriorly at an angle of 45 degrees, then carry it into the throat close to either side of the uvula, back of the soft palate, being careful not to touch the posterior wall of the pharynx, keep the left hand close to the left side of the mouth, so as not to be in the way of seeing, then with one or two quick but prolonged pressures of the bulb we will have covered the post nasal cavities There are but very few patients who can not in this way tolerate treatment (if warm oils are used) without gagging, or not take more time than it would in a manner not half so complete

It requires but little time to teach patients how to make applications in the nose anteriorly, by setting the point upward as shown by No 3, Fig 1, placing the thumb of the left hand under the tube close to the movable point as shown in Fig 2, the fingers being placed upon the upper surface of the tube, then carry it into the nose until the thumb rests upon the upper lip, using it for a steadying point and gauge as to depth of entrance, elevate the cup above the level of the nose so as to have the advantage of gravity, then give two or three quick but prolonged compressions of the bulb and the application will be sufficient, in the majority of cases, when not, in a short time they may be taught to make them posteriorly, they quite soon learn how to drop the tongue in the floor of the mouth or hold it down with the tubes of the spray producer Many can use it without seeing, but they can see how to use it by the use of a mirror and keeping the hand that holds the in-

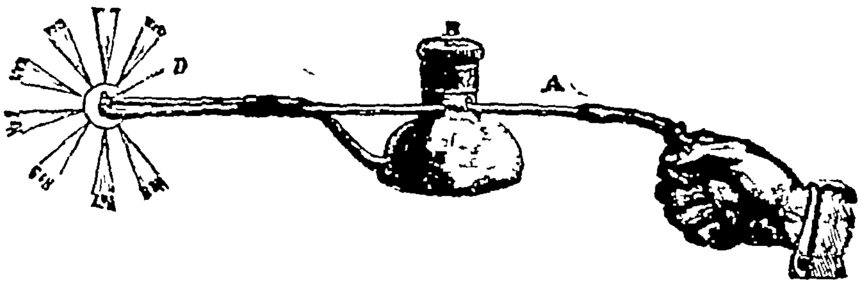

Figure 1

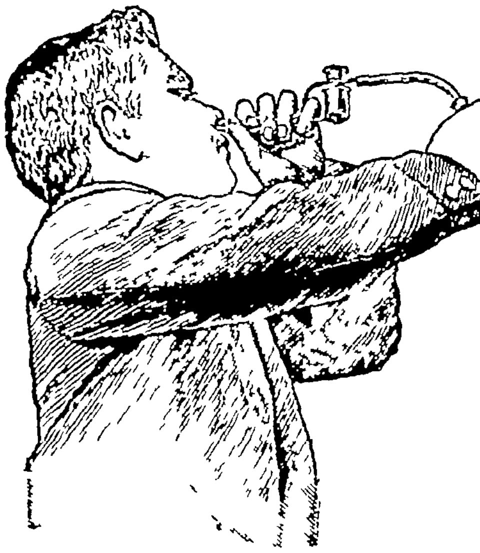

Figure 2

strument to one side as shown by Fig 3, so as not to obstruct the light

Children who do not breathe easily through the nose may be relieved by a few applications of warm oil This cleans out the nasal cavities and allows them to breathe through the nose In treating children it is best to leave the point of the spray straight or nearly so Applications should be made while lying down Place the index finger of the left hand close to the point, and rest it upon the child's upper lip, then compress the bulb a few times which will fill the nose with warm oil

I believe that by following up this plan of treatment with children when they have colds they will have much less trouble when they are older When treating an acute condition, no irritating remedies should be used Warm aseptic oil is all that will be beneficial locally If warm enough it will soothe, protect and cause a contraction of the capillary vessels, thus relieving the congested parts

In simple chronic nasal catarrh, there will be many cured, and marked benefit received by all, from spraying a warm aseptic oil over all parts affected If the discharge is purulent or tough or ropy, first clean with a solution made from Seilers' tablets, then apply the oil, the addition to the oil of an alkali or antiseptic will be of service if not made too strong In cases of hypertrophic nasal catarrh where inspiration is interfered with, beside the local treatment given, the same as in simple chronic rhinitis, tissue may have to be removed It is no use to treat these cases for a short time They must be treated or treat themselves every time there is an acute attack By so doing, instead of growing from bad to worse, an improvement may be expected

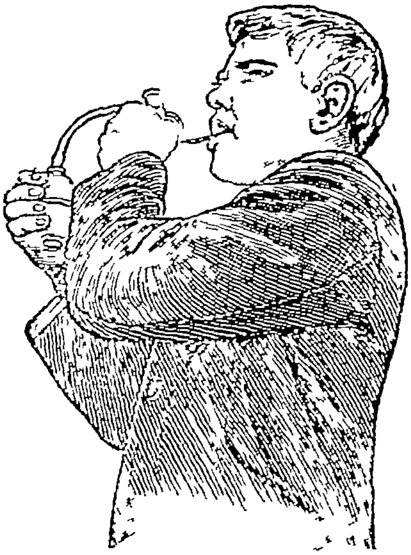

Figure 3

This I find patients will be satisfied with, if it is so represented to them, instead of promising definite cures

In treating atrophic nasal catarrh the essential thing to do is to clean the parts It may be necessary to use Dobell's solution or a similar one to remove the crusts, but generally the better way is by direct applications (as before described) of oil, for the reason that we have no osmotic action, no increase of desquamated epithelial cells, no inflammation set up by throwing it into the middle ears, all of which we may have by using watery solutions

It is often beneficial to add to the oil some form of an antiseptic such as oil of wintergreen, camphor, menthol, or oil of eucalyptus, five drops to the ounce, etc The list of antiseptics is a long one to choose from, and the odor and taste of each differ so much, that we need not have any trouble to carry out the proper line of treatment and make sufficient changes to satisfy the mind of our patient I treat them until I get the parts under control and then teach them how to make the application

A dentist can scrape off incrustations from a tooth, but he can not give the fine polish to the enamel that it had The rough condition left serves as a predisposing cause for the return, but if a brush is used from time to time the incrustations will be prevented Just so with the nasal mucous membrane after there has been a chronic inflammation of it The original condition can not be restored by any course of treatment, but by treatment from time to time the serious difficulties that would result therefrom may be prevented and the patient made comfortable through life This they are entitled to, more they can not procure, and they will be content unless promised a radical and permanent cure In a healthy condition the nasal mucous membrane furnishes about sixteen ounces of fluid every twenty-four hours By it the material filtered from the air or accumulations from any other source are carried through the nasopharynx into the esophagus and stomach unnoticed But when from any cause an irritation or inflammation is set up, the amount of fluid may be increased or lessened If increased, soothing applications must be made to relieve the irritation or inflammation

If the amount of fluid has been lessened, we find desquamated epithelial cells, mucous corpuscles, and the impurities taken from the air remaining in the nasal cavities, and we must accomplish what the diseased condition prevents being done in a natural way If the case be one that has not progressed too far, by using a solution that will cleanse, soothe and protect the parts, they may be restored to almost a natural condition

Where the pressure of adventitious tissue has caused absorption of the glandular elements which prevents the process of exosmoses from the numerous blood vessels, the sooner a patient realizes he must put his nose in the same line with his hands and face to be cared for, the better off he will be No one would expect to keep the face continuously clean by washing it for a month or two, neither can the nasal cavities by any kind of treatment for a short time, (when the conditions just described exist) be kept continuously in a clean condition, which must be, in order to have any hope of improvement or prevent an increase of the difficulty

I have long since arrived at the following conclusions that surgical work must be done in certain cases, constitutional treatment is necessary in some, local applications in all, and that the remedy should reach all parts affected and in itself or the means by which it is applied, shall be non-irritating, and that it is useless to prescribe a spray producer for a patient without first teaching him how to use it

---

Dear Doctor —Please direct the attention of your friends to our JOURNAL We will be pleased to send sample copies to any names you may suggest

HYPNOTIC INSANITY

Read before the Marion County, (Ind) Medical Society, June 11, 1895

BY E D MOFFETT M D
INDIANAPOLIS, IND

In writing upon this subject, I wish to show the true merits of hypnotism, and to congratulate my profession upon the fact that we have been slow to indorse this one fad which came to us a few years ago with such wonders in the cure of many diseases Yes, the greater body of our profession discard it altogether

The hypnotic state is a diseased condition of the mind, and I feel that it is possible to prove that it is the worst form of disease—that of insanity

Hypnotism, mesmerism or suggestion is that condition of body or state of mind which is characterized by an apparent sleep with a perversion or destruction of the will, or that part of the will which governs the reason and judgment For example, the person under its influence will stare into space or with eyes closed seems to be perfectly unconscious of himself or of his surroundings, and will follow the dictates of a supposed hypnotizer, no matter how absurd and contrary to the sense of propriety

Suggestion is the primary law of all knowledge Therefore know that we are handling only the extreme possibilities of this law All knowledge is derived in three ways suggestion, deduction and induction In our early childhood we know nothing except it be imparted to us by friends, or by some object, as a tree which suggests some thought to the novice, thereby a state called memory is created Likewise a mirror or the gentle stroking of the forehead by an operator with thoughts expressed, will produce the same state of mind called suggestion And when that individual mind has lost, by this process, the will power governing judgment and reason, we have what is called true hypnotism Please to remember this definition, for soon we will find what a wonderful power the law of suggestion, or the perverted condition of it which misleads, has in this world

Advanced in years we begin to reason by deduction and herein lies the power of theorizing If you remember, a few years ago I read you a paper upon the subject of "Theory in Medicine," which brought out some of the fallacies of the deductive method of reasoning in medicine

By induction we have much of our true knowledge to be thankful for In suggestion we have three stages receptive, somnolent and cataleptic First, to be able to receive a suggestion the mind of the individual must be willing to receive Here again is the will brought into power To receive or not to receive is the question Now what harm has a thought or state of mind upon an individual who has the equilibrium of mental forces well balanced by the will? None whatever Right here is the beginning and ending of a weak and strong mind He who stops to reason is wise, no matter how imperfect the conclusion But he who receives and reasons not (with the will as the governor of the mental engine) is prone to mental aberrations Whether the individual has entered a physical drowsy stage of hypnotism or not, if we have that state of mind forces, after receiving an impression from a thought or an object, which is embodied in the definition given, we have that mind hypnotized—diseased Diseased because no physiologic laws, either physical or mental, can be destroyed without being pathologic

The complete somnolent stage is that condition in which we have catalepsy, and what is called suspended animation And those cases which from severity of pain become unconscious for an indefinite period and then regain consciousness without any apparent shock being the cause

Now let us see if it is not a logical conclusion that the mental state and causes of insanity are identically one and the same phenomena as perverted suggestion

So far as the mind and thought is concerned, insanity is the loss of the proper coordination of mind forces It is an impairment or destruction of the will governing reason and judgment Example a brain takes on a suggestion from any cause, as some friend is trying to kill that individual If this be not so, and the reason and judgment governed by the will of this case can not be convinced by friends or by a logical conclusion of self-reasoning this brain is unbalanced

Whenever a brain takes on a thought once, it is a well-known law for it to be recalled at will and in time can become automatic To have this condition to take place at unusual times we have the state called auto suggestion, or the power of the brain to repeatedly place itself in a state or condition of thought unconscious to the individual Actions usually follow thoughts, and this is the reason we have to have asylums One who has had hypnotism practiced upon him is very liable to get into the state of auto suggestion Is not this true of all the insane, that there is a constant recalling of some absurd thought? And this is produced by the laws governing hypnotism—the reason and judgment at fault. Consequently, the insane are unnatural suggestable cases Here is my argument "Things equal to the same thing are equal to each other" Hypnotism equals the destruction of the mental force of the will, which holds in balance reason and judgment Insanity equal the impairment of the same forces Therefore hypnotism is insanity, conversely, insanity is hypnotism

Society is all agog with this dreadful disease Look at the youth who persists in dissipation at the dance and other enjoyments when his friends and physician try to bring him to his proper senses And do you say that the law of suggestion which has misled into supposed pleasure and enjoyment is not the cause of all this? A well-balanced brain is one that is temperate in all things

Again, a young man is pushed to extremes financially to keep up with society Soon his salary is too small to meet demands His mind wanders, embezzlement, exposure, prosecution and conviction results, and society laughs Society has been the medium of suggestion The law provides for the poor criminal, but the beautiful mirror which has suggested his downfall still goes unbroken Let a corporation, a body or society be the cause of one's downfall and it is all right But if an individual is the medium of one's errors it is quite a different thing, as in the following a man with reason unbalanced, plots with one somewhat weaker than himself to commit a murder The man who will use his erroneous reasoning and influence to cause another to commit such a crime, probably for a paltry sum, is hypnotically insane The suggestion being a hate, jealous love or desire for some special gain and the like, which has led his mind astray Is not the will here at fault?

The one who does the deed is hung for being a suggestable subject, insanely so While the other is executed for discovering the weakness of his brother

This is what the law does with those who are not insane enough to let their neighbors know of their weakness in time to commit them to an asylum Some time ago a man called at my office for dates of an injury received by a bucket falling from a building in course of repair The injury was a glancing one, and took off a part of the scalp on the top and front part of the head No concussion or shock followed He is now preparing for a suit for damages In course of his remarks he declared that the injury had affected his brain and left him in such a state that he might kill me then if he should get mad I wish to tell you that the only relation of his injury to present mental conditions is that of suggestion by a supposed permanent injury to the brain, an impossible condition He is insane upon this subject and hypnotically so The poor man is prone to go on with his auto suggestion until he does some one bodily harm

This is the form of insanity which has produced our assassins, Guiteau, Mayor Harrison's murderer, etc Just to think, in this day of learning that there is no law to take hold of people who are possessed of threats against their brother or against themselves—cases of suicide and its attempts We are much in need of statutory provisions for such people

Even religion is not exempt from this disease Take the early days of persecutions, crusades, witchcrafts and its punishments, all produced by a want of proper brain balance, but no phase of society is more rapidly getting out of the turmoils of this disease than religion—and doing so by consistency and education If there is one phase of society which is slow in progress in the right direction, it is that of politics So little of true governmental principles are taught to us in early youth in school, we become grown and do very little reasoning for ourselves We are partisans because of the law of suggestion and not much force or reasoning is expended in such attainment Men go wild over an argument during a campaign or over some great financial question, the conclusion proves the premise, but too often the premise is wrong

Our last panic was nothing more than an epidemic of wild suggestion that spread over our country like a cholera germ And the same disease played havoc with the LIII General Assembly, and with our late Indiana Legislature Germs of poisonous thoughts get into the brains of men and they spread worse than an epidemic disease

Medicine comes in for its part Do not think because we are last that we are least Many examples could be recited, but you can recall many, and time forbids

Look at the pandemic effect of the "elixir of life," the much abused operation upon the cervix in the past, and the extreme of supposed cures to which Battey's operation has been subjected, many of the untimely and hasty therapeutic experiments, etc Why do we not all know the truth first and then tell it, instead of proclaiming a thing true, then theorizing to prove it?

A very prevalent class of cases are those of abnormal sexual relations I refer you to the learned treatise on "Psychopathia Sexualis," by Kraft-Ebbing, translated from the German by Chaddock, a book well worthy of the perusal of the profession

Hysteria, melancholia, catalepsy I believe to be in different stages of suggestion, usually caused by some impairment of one or more of the vital organs other than the brain Disease of the liver can produce marked melancholic insanity I never have tried to practice hypnotism, but have seen several cases by others and a few cases capable of producing the state themselves While in the hospital we had a case of true catalepsy which could be easily put into the state by a hypodermic of a small portion of morphia I could not trace the history of this case, but I believe the auto-suggestion was produced by an impairment of the mental function

A case of labor under my care was completely hypnotized by the severity of the pains She lay with eyes open staring into space, pupils contracted, pulse and respiration normal There was only a slight movement of hips during the pains When she awoke from her partially cataleptic state she was surprised to know the labor had ended Three days later she went into this state again and continued so for three hours—probably produced by a suggestion on my part that if she did not take better care of herself she would have a chill and might die

Some time ago I attended a spiritualistic séance After a short and literary effort upon the part of the spiritualist, she tried to hypnotize herself by looking intently for a few moments into one corner of the room She should have selected a bright object, for I could readily see she was not an auto suggestable case She made a failure of the above, but she soon began to get communications from spirits for a few of the faith believers present And here is another of our hypnotically insane beliefs The uncontrollable desire for smoking and drinking is mental disease also

Treatment —If my argument be true, every State and nation should make laws prohibiting the public exhibition of hypnotic cases It should be made a penal offense to try to induce it other than for a cure of the insane And from what little can be accomplished with it in these cases, there will not be much of this mal-suggestion used

Nevertheless, there is a good lesson taught in Chaddock's "Psychopathia Sexualis" From a number of the sexual perverts described by him, we draw the conclusion that the cases are insane upon their particular phase of sexualis And please not to forget that these people get into this state by continually harping, thinking and recalling their abnormal thoughts and putting them into action All this by *auto suggestion — thought* and action repetition Where is the will, reason and judgment of these cases? Talk about the world not being full of insanity!

Some of you are probably thinking why we are not all incarcerated Here is a fair solution to the problem It seems to be a case where the majority rules, or to the victor belong the spoils Chaddock tells us that many of his cases have been relieved and cured by the practice of creating a new train of thought and a regenerated will, by proper suggestions, while the patient was under the hypnotic influence Is there not a thought revealed in these cases worthy of consideration? Here it is all of these cases were far advanced in immoral dissipations, who sought him for treatment They realized their insanity and sought relief Their will was not wholly destroyed A cure was effected in a good per cent of cases

I believe that herein lies a system which might prove wonders with the incarcerated insane That is, to make them by some process, realize that they are mentally diseased, and that there is a cure for many, sick as they are, and if they could be made to realize this and seek the remedy with as much earnestness as did Chaddock's cases, we might have a place for true hypnotic suggestion but not "hypnotic insanity"

16 W New York Street

REMARKS ON APPENDICITIS

Read at the meeting of the Northern Tri State Medical Society at Coldwater, Mich, July 9, 1895

BY J H CARSTENS, M D

PROFESSOR OF OBSTETRICS AND CLINICAL GYNECOLOGY DETROIT COLLEGE OF MEDICINE CHIEF OF STAFF AND GYNECOLOGIST HARPER HOSPITAL PRESIDENT OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS ETC

DETROIT

Appendicitis is talked of and written about a great deal, and when I go around with my professional friends who practice in the small cities and villages, they all say, "Appendicitis is a great fad We seldom see a case, why is it that you see so much and operate on so many, while we rarely see a case?" Some of them even, who look at everything with a pessimistic eye, say that many cases are operated upon and reported that are not cases of appendicitis at all Some of them have quite a large practice and only once in a while do they see a case that they call appendicitis, and how others can see dozens and hundreds a year is utterly beyond their comprehension But the solution is very easy, from what I am able to find out, from the number of cases of appendicitis occurring in the course of a year in a large city, I have come to the conclusion that about one case of appendicitis occurs to five thousand population, when we consider that throughout the country there is only one physician to less than five hundred inhabitants, which means less than one hundred and fifty families This is the average, some have a great many more and some a good many less, but a physician who has three hundred families, I will say, has a pretty good practice, and if any one should have double that number, he has an extraordinary practice A physician with three hundred families, that is, a good large practice, would have about a thousand people under his care, and if the above statement of one case of appendicitis in five thousand population is correct, you would naturally conclude that the average physician with a fair practice would only see a case of appendicitis, on an average once in five years

Perhaps my estimate is too high, say a case of appendicitis occurs to every two or three thousand inhabitants, and it certainly does not occur any oftener, then it would still hold true that the average general practitioner would not see a case of appendicitis but once in two or three years Now, let us go one step farther and bear in mind that appendicitis is sometimes a very obscure disease, which the general practitioner will very often overlook, and no blame can be attached to him for that, as he sees these cases so seldom We can furthermore see that the statement of the general practitioner, especially of those living in the country and the smaller towns, that appendicitis is a rare disease, is perfectly true from his side of the question Still, the field of medicine has been so thoroughly and repeatedly gone over, the cause, the pathology and the treatment of the general run of diseases, that the more rare and obscure diseases are now attracting wide attention, and he is *the best physician*, who can not only properly diagnose the common everyday cases of malaria and typhoid fever, dysentery, pneumonia and so on, but he, I say, is the best physician who can properly diagnose and institute the proper line of treatment in those cases which are obscure and less common like appendicitis, like pus tubes, and like renal and hepatic calculi

In the large city, where the daily press is always on the lookout for news, prominent citizens are sometimes attacked with this disease, the papers take notice of it, and this occurring a number of times in the course of a year finally attracts the notice of the laity and they learn on inquiry from their family physician about the signs and symptoms and causes of this disease The general practitioner is frequently asked by his patients about this disease, and thus his attention is more vividly attracted, he is constantly on the lookout to detect it when he has cases with symptoms pointing to this morbid condition and will call in other physicians in consultation so as to be sure Hence, in a large city, few cases escape without being properly diagnosed Still, there are general practitioners who do not have it sufficiently impressed upon their minds, that *peritonitis means appendicitis* They are impressed with the idea that appendicitis virtually does not exist, and let me say right here, that I exclude pelvic peritonitis caused by pus tubes, or puerperal peritonitis caused by septic infection from the uterus I refer to the so-called idiopathic peritonitis, which is always caused by appendicitis—that is to say, in twenty-four times out of twenty-five and the twenty-fifth case is that exception, which always proves the rule In other words, ninety-six cases out of a hundred are caused by appendicitis, while four cases in a hundred are caused by perforation of the bowels from ulcerations, malignant growths, etc And if the general practitioner would only have *his mind sufficiently impressed with this one thing, that peritonitis is appendicitis*, I know he would be astonished at how much oftener he will find appendicitis than he ever thought possible If he will carefully inquire into the history in a vast majority of cases, he will find that they have had one or more previous attacks The attacks may have been slight, perhaps they were only laid up for a day or two with what they called colic, but on careful inquiry you will find that the patient had severe colicky pains in the right inguinal region, which is attributed to cold or indiscretion in eating, and be passed over without having consulted a physician Perhaps he has had a number of such attacks On careful examination, the physician will find that the patient has more or less pain over the whole abdomen, but that there is one excruciatingly painful little spot midway between the umbilicus and the crest of the ilium—the so-called McBurney spot

There may be tumefaction, generally not, because as a rule the appendix is behind and the cecum in front, containing more or less gas, so that no dullness on percussion can be detected Sometimes vomiting ushers in an attack, the fever is sometimes high and sometimes quite low, I have seen cases where perforation occurred with temperature over 99 5

It is only by being constantly on the lookout for this disease when you have cases of abdominal trouble that you detect it, slight cases will very often be overlooked

During the last six weeks I have had a few cases which might prove interesting

Case 1—Miss A, aged 25 first attack eighteen months ago She was laid up three months in bed, then two more slight attacks, then another attack last June, and finally took to bed until September, then again had another attack in February The sixth attack induced her to enter Harper Hospital and submit to an operation Operation was performed May 18, in the usual way The appendix was large and strictured at the junction of the cecum, not perforated, and was removed and the incision closed with buried kangaroo tendon, no drainage She was up on the twelfth day and has made a splendid recovery

Case 2—Mr W, aged 18, had an acute attack of three days' duration with temperature 103 He had had a slight attack four weeks previously, but this had been overlooked He was immediately taken in the ambulance to Harper Hospital and operated upon May 26 The appendix was ruptured in the middle but was walled in by exudate, it was removed, a gauze drain was used and a part of the incision closed with silkworm gut sutures Recovery uninterrupted

Case 3—Mrs L aged 21, has had four attacks and agreed to go to Harper Hospital Wednesday evening to be operated on Thursday Tuesday afternoon she was suddenly taken with a fifth attack and I had her immediately conveyed to the hospital in the ambulance and operated on that night, May 28 The appendix was very large, full of muco purulent fluid and on the point of rupturing in one place, where the mucous and muscular coat were ulcerated, no drainage Buried kangaroo tendon was used to close the incision She went home on the thirteenth day,

Case 4—Maud H, aged 10 first attack of ten days' duration, large tumor filled with pus She was taken to the hospital, the tumor simply opened and a large amount, (more than one half pint) of stinking pus was removed The cavity was cleansed and drained and the incision partly closed with silkworm gut sutures She made a splendid recovery and went home on the twelfth day This operation was performed on June 22

Case 5—Mr B, aged 30, was taken with appendicitis in April I saw him in consultation, but considered the symptoms so mild that no operation was deemed necessary, unless serious symptoms developed In a week or ten days he seemed to be all right, but was again taken with severe pain in the right side This would subside with hot applications and he would be around again for a day or two, and then have another attack, and so continued for two months I again saw him and pronounced it relapsing appendicitis I operated on him July 1 at St Mary's Hospital and found the case as stated Removed the balance of the appendix and closed the incision with buried kangaroo tendon except for about half an inch, where I left a gauze drain This was removed in forty-eight hours and a small rubber tube inserted He made an uninterrupted recovery

Case 6—Mrs W, is an unfortunate woman I had operated on her two months ago for pus tubes She went home and seemed all right for four weeks then began to have pain in the abdomen especially on the right side, her temperature ran up and came down again to about normal she became weaker and weaker and could retain no nourishment I was called in consultation and diagnosed appendicitis She was immediately taken to the hospital and I found the appendix large inflamed and adherent, but unruptured This was removed and the incision closed Operation July 2

These few cases and it is hardly necessary to say that I had none who died, or I would report them also, occurring within six weeks, will again make you wonder where we get them Some of these patients have come several hundred miles, and the territory covered by them embraces a population of two million or more And when I consider the number of cases operated upon by my colleagues, I am enabled to make the assertion I did at the opening of this paper, appendicitis is not so frequent as it is supposed to be, and still it is more frequent than many practitioners believe, as they never look for it

In resumé I would lay down the following rules

1 That the general practitioner with a good fair practice will hardly see more than one case a year on an average

2 That peritonitis always is appendicitis and will be readily diagnosed by every practitioner if he will only look for it

3 That all cases of appendicitis should be operated upon as soon as diagnosed, because the danger is almost *nil* before rupture, but after rupture even an operation will not always stay the progress of the septic condition

Of course, I admit that some cases will never recur, and if we operated on every case, we undoubtedly would operate on some cases that would get well without an operation, but we can not tell which case will recover and have no relapse, and which will not, and by waiting until rupture has occurred many cases will die which by prompt surgical interference would be saved

SAVING LIFE OF CHILD DURING LABOR

Read before the Montgomery County Medical Society, September 1894

BY E W KEEGAN, M D
CRAWFORDSVILLE, IND

Napoleon asks the question, Is the route practicable? and the answer was, It is barely possible to pass The obstetrician may well ask, Is the way ample? is the pelvis of the mother normal? We may have any degree of abnormality to the most complete dystocia, compelling us to say it is impossible for a living child to pass It is generally believed an obstetrician's duty to perform Cæsarean section or symphysiotomy for the child's safety, knowing they are to day safe operations if the technique of their performance is observed, and the mother's life is less jeopardized than by any other method of delivery Theory has long held the view that, in making a sacrifice of life, that of the mother should be second to the child, nor can we expect professional support in declaring this a great injustice Does not the mother, as a rational being, enter the marriage relations with full consent and knowledge of the consequences that follow gestation and delivery? She so delivers her future for the intentions of marital life Why should we, as accoucheurs give consent to laws that do not equalize the relations between child and mother? Do you not see from the commencement of embryonic life the child is but as so much clay, shaped by the greatest sculptor, Nature's hand, whose nicety of touch and delicacy in outlining finishes and brings to birth the beginning of a being which has been proved to develop into the highest type of animal life, and should it not have the same consideration? Why, then, is it not as criminal to destroy the life of the child, as the mother, without resort to means for its life as well? It is sometimes considered justifiable to take life in self-defense, for it is not the mother who is supposed to destroy life but the accoucheur

We have now given us, by advanced science, desirable means of combating with the difficulties of years gone by, to where an amputation is no longer looked upon to be followed by gangrene and death Time has proved beyond doubt the effects of antiseptic surgery

Cæsarean section has lost much of its former magnitude When the dystocia is not so great, but sufficient to make impossible the delivery of a living child without unjustifiable compression of the head, we should resort to symphysiotomy, an operation attended with much less danger to the mother and general safety to the child Though an old operation, it has, in the past two or three years, under aseptic care, given brilliant results and will perhaps render Cæsarean section rarely necessary I will not make a general resumé of all accidents incurred in parturition, endangering the child's life The amplitude of the mother's pelvis deserves attentive consideration, but as the range of variance is so broad and conflicting when contrasted out of the lying-in chamber, I would advise a careful study of its anatomy and differential points when in attendance, for they have a certain individuality that only experience can give explanation of, where authors read so confusingly

Next in importance we note presentation In the vertex presentations we will first consider face anterior, which is considered very unfavorable in multipara but more so in primapara If an early diagnosis can be made and dilatation sufficient by placing the patient in an extreme Trendelenburg position, introducing the hand well up to the shoulder, rotating the body of the child with its head, avoiding undue force, we can convert a face anterior into a face posterior This is often facilitated by the patient lying on the side toward which the rotation is directed I use the same position for shoulder presentation, pressing the shoulder well up and with the hand externally carrying the child's head well over the superior strait and holding it in position until well engaged This treatment I learned from Dr M B Wright, of Cincinnati, many years ago and find it preferable to turning In presentation of the hand, the only alternative is to turn, bringing both feet down under full chloroform anesthesia, directing an assistant to hold the child well up, so that if the oncoming head does not pass readily, forceps can be applied and immediate delivery made It is culpable negligence to allow a child to perish for want of assistance, and no accoucheur should deny himself such aid as a physician can render when circumstances make it possible over any other In placenta previa it is generally preferable to tampon until dilatation is sufficient If the engaging head does not control hemorrhage, apply the forceps and make rapid delivery, immediately introduce the hand into the uterus and deliver the placenta, using friction to excite contraction If this does not check the hemorrhage, compress the abdominal aorta until the action of ergot, hypodermically, can be secured , small pieces of ice, injections of per sulphate of iron with peroxid hydrogen , in failure, the first can be used

In prolapsus of funis, many suggestions have been offered, all with little success In my experience the knee chest posture and the hand have given the best results governed by the circumstances of the case, and in no instance have I seen any of the appliances recommended of any avail As an oxytocic, I have found quinin valuable in increasing the uterine contractions, though not capable of inciting them If it does not increase the pains, in two or three hours apply the forceps and deliver In the use of them, I believe a suggestion of my own will be valuable to those making forceps delivery never make traction unless you have an assistant Make firm pressure laterally and over the fundus uteri, continuing the pressure until told to desist For this reason, I offer this suggestion it is known to every obstetrician that the pains subside spasmodically, doing so while traction is being made The uterus becomes relaxed and the child, in an effort to force the head from the forceps after the uterine pressure is taken off, breaks its neck, but by the observance of what has been given, such an accident is avoided In eclampsia, when dilatation is incomplete, I dilate either manually or instrumentally under anesthesia, delivering without delay, using all prophylactic means to guard against sepsis I regard the risk to the mother and child as materially lessened, for more children are lost during labor from dilatory procedure than through active interference You all know that if we wait several hours for dilatation, injury to the brain, convulsions, is generally fatal to both In a general summary of this paper, my desire is to impress upon you the point that a ready conception of, and ability to combat all or any of the emergencies occurring in the lying-in chamber, governed by calm judgment, quick action and mechanical ingenuity are the sequela of a successful accoucheur

NECROLOGY

George A Mursick, M D , died at his home in Nyack, October 17, of diabetes He was born in New York city in 1834, and was graduated from the College of Physicians and Surgeons in 1860 In January, 1863, he entered the Union Army as assistant surgeon He was promoted to be surgeon in charge of the General Hospital at Duvall's Cliff, Ark , in November, 1864 and became medical purveyor of the Department of Arkansas in April, 1865 He went to Nyack to practice in 1869 He leaves a widow and two sons

Adelbert F G Kuehn, M D , of New York city, died at his home October 22, of appendicitis He underwent an operation at St Mark's Hospital two days before Dr Kuehn was born in Pittsburg in 1852 He was a graduate of the School of Pharmacy and the College of Physicians and Surgeons, in class of 1892 He was a member of the Harlem Medical Association, and the New York County Medical Society He leaves a widow The place of interment was Wilkesbarre, Pa

J M Pride, M D , of Algona Iowa, October 18 ——E J Cook, M D , of Milwaukee, Wis , October 31, aged 76 ——D B N Fisk, M D , of Amherst, Mass , October 28, aged 53 ——Amos Fowler M D , of Albany, N Y , October 23, aged 76 ——W H Sedgwick, M D , of Granville, Ohio, October 25 ——T M Tilford M D , of Horse Branch, Ky October 27, aged 72 ——Joseph Daffron Schoales, M D , of Philadelphia, October 24, aged 53 ——J A Phillips, M D , of Pittsburg Pa , October 25, aged 63 ——Thomas F Young, of Brooklyn, N Y , October 26, aged 30 ——Francis W Gibson, M D , of Columbia, Mo , October 17, aged 32

Incorrect Opinions no Ground for Rescission of Settlement — The Supreme Court of Minnesota states, in the case of Nelson v Minneapolis Street Railway Company, decided May 24, 1895, that the plaintiff having presented a claim for personal injuries sustained by her while a passenger on its cars, the defendant employed physicians to go and examine her, and report to its claim agent as to the extent of her injuries The physicians had no other duty to perform, and this was the extent of their authority At the time of such examination, in response to plaintiff's inquiry whether they thought she was seriously or dangerously injured, the physicians replied in the negative, saying she would soon be all right again Afterward she settled with the defendant, and executed to it a full release and discharge, relying upon the statements of the physicians It subsequently developed that she was much more seriously injured than the physicians in their opinions expressed to her, but there was no evidence that these statements were not their honest opinions, given in good faith Under these circumstances, the court holds that the fact that the opinions of the physicians proved to have been incorrect, constituted no ground for a rescission of the settlement and release

THE PARASITES OF MALARIA

The literature upon the parasitic origin of malarial fever, though already very extensive, has received an important addition by the publication of a systematic study of the malarial fevers of Baltimore and its vicinity, by THAYER and HEWETSON,[1] assistants in the medical clinic of the Johns Hopkins Hospital

The study begins with a historical summary of the more important literature concerning the malarial parasite, and the table of references arranged in chronologic order at the end of the article shows that 359 separate works have been considered, all treating of some aspect or other of malarial fever since the recognition of its parasitic cause

The original portion of this article consists of a general analysis of 616 cases of malarial fever observed in the Johns Hopkins Hospital from June 14, 1889 to Jan 1, 1894 As regards the age of these patients, comparison with the ages of a similar number of non malarial patients, selected at random, at once shows the greater frequency of malarial fever among children and young adults This, the authors regard as probably due, not so much to a greater susceptibility as to the fact that the young adult is more exposed to malarial influences—remaining out of doors in malarial districts at night, etc There were about four times as many male as female malarial patients and this evident discrepancy is also explainable on the theory that the ordinary avocations of the men subject them to greater exposure than the women who, remaining in the house, are oftener spared

While the per cent of ordinary colored patients, taking the cases at random, was 12 2, the per cent of colored malarial patients was only 4 7, the figures tending to uphold the generally accepted view that the negro is much less susceptible to malarial infection than the white

As regards the season, it was found that while malaria may occur in any month of the year in Baltimore, yet nearly one half the cases were observed during the months of September and October In the majority of the cases the examination of the blood was conducted with the fresh specimen and it may be said without entering into any descriptive details, that the authors firmly believe that there are distinct varieties or types of malarial parasites which are not interchangeable but distinct varieties, though closely allied to one another, biologically combined infections, with parasites of different varieties may occur, but they are rare—less than 2 per cent of all the cases studied

Of the 616 cases studied by these writers, the type of the parasite was definitely differentiated in 542, and of these 150 were instances of single tertian infection, 188 of double tertian, 2 of single quartan, 3 of triple quartan, 188 were examples of infection with the aestivo autumnal parasite and 11 were instances of mixed infection with aestivo-autumnal and tertian parasites Further statistical tables show in an interesting manner, how the type of the infection becomes more and more severe as the summer and fall approach, thus, in the first half year only 5 aestivo-autumnal cases were observed, while in the last half 183 cases were observed, and as the seasons indicated advanced, the cases of double tertian infections also became more common

In the course of their studies the authors reach the conclusions that the tertain type of fever depends on the presence in the blood of a parasite that passes through its cycle of existence in about 48 hours The segmentation of this organism, at intervals of about 48 hours, is always associated with a febrile paroxysm Frequently, owing to the presence of two sets of organisms, there are quotidian paroxysms Quartan fever, rare in Baltimore, depends on a blood parasite that undergoes segmentation which is associated with a febrile paroxysm every 72 hours Double or triple quartan infections are possible In regard to the aestivo-autumnal fever they conclude that it is due to the organism described by MARCHIAFAVA and CELLI, but that the cycle of existence of this parasite has not yet been followed out in an entirely satisfactory manner, it probably varies from 24 hours or under to 48 hours or more, the main seats of the infection with this organism are, apparently, the spleen, bone marrow, and other internal organs, but few stages of the development of the parasite being ordinarily found in the peripheral circulation This organism causes fevers that vary greatly in their manifestations There may be quotidian or tertian intermittent fevers, or, more commonly, more or less continuous fever with irregular remissions

---

[1] The Malarial Fevers of Baltimore Johns Hopkins Hospital Reports, Vol V, 1895

While Thayer and Hewetson reach reasonably definite and apparently sound conclusions as regards the distinctness of the various types of material parasites and their relations to the clinical forms of malaria, yet they have to point out that the nature and the relations of certain bodies observed in the blood of malarial patients are still, in their opinion, undetermined This is especially true as regards the nature of the flagellate bodies which may develop in all types of malarial fever, concerning their nature and relations nothing definite is yet known It also appears that certain crescentic bodies, associated with the aestivo-autumnal parasite, are not yet thoroughly understood

Concerning the treatment of malaria the authors had abundant opportunity to observe that the specific action of quinin upon the three varieties of the parasite is indeed undoubted Quinin exerts this remarkable influence most strongly when the parasite is undergoing the process of segmentation and before the fresh segmented forms have had time to enter into new red blood corpuscles It is consequently best administered, then, just before the beginning of a paroxysm, if we wish to obtain the greatest effect with a single dose The specific action of quinin is much more rapid and certain in the tertian and quartan fevers than in the aestivo-autumnal infections

ABDOMINAL vs VAGINAL HYSTERECTOMY

The technique of hysterectomy has been so much improved of late years that the operation which was during the first quarter of the century not accepted as a legitimate one by the majority of surgeons, has now been admitted to be a standard operation, and in suitable cases an imperative one The method of performance of hysterectomy is now under discussion, and those practicing that branch of surgery termed gynecology, seem to be divided into two opposing camps, one favoring the abdominal method of extirpation of this much suffering organ, and the other the method through the vagina As in many other questions raised by specialists, it must be settled on the general principles of the branch in which it is included, and it would seem as if there were no necessity for acrimony of debate on this subject if we could once agree as to the facts, and if it shall be proved by careful statistics that one method is safer than the other, so far as its immediate effects are concerned, that it is as thorough, so far as the remote effects of recurrence of the disease for which the operation is performed are concerned, then there should be no question as to the adoption of that particular method

And just here authorities differ as to which is the safer method We may easily exclude all of those cases of enormous fibroids in which the uterus and its attachments are too large to be removed through the vagina, as nobody would think of performing vaginal hysterectomy in such cases, but in those cases in which we have a carcinoma involving the cervix or body of the uterus, in which there is no undue enlargement, it seems reasonable to suppose that if by the process of enucleation, a smaller wound and reduction of the liabilities to infection, we can remove the uterus through the vagina, there should be equal promptness in accepting that operation But the truth is is that each case must be decided on its own merits and the particular characteristics of the case In cases of fixation of the uterus and where the adjacent pelvic glands are seriously involved, it is obvious that the vaginal route does not afford access to all the diseased tissues, and that the mere removal of the uterus by enucleation is inadequate for the removal of the disease The vaginal route, too, lest extreme care be taken, is much more liable to convey infection into the general cavity than a clean abdominal incision under the usual aseptic precautions, and a careful study of the papers presented by the respective disputants would seem to resolve themselves into the proposition that as cases differ so must the treatment differ The knights of old fought about the shield whose surfaces were of gold and silver Each looked on the side next to him and affirmed the shield to be gold or silver, as the case might be, and they were both right and both wrong And so the surgeon who does not recognize and appreciate that his choice must be guided absolutely by the nature of the case and the conditions then present, is liable to be sometimes right and sometimes wrong

Dr Levi Cooper Lane of San Francisco, Cal, first performed vaginal hysterectomy in this country in 1879 (*Pacific Medical and Surgical Journal*, 1879, vol xxi, p 489) Dr H A Wrisberg of Gottingen, excised the uterus through the abdomen in 1787

COMPLETE EXCISION OF PATELLA

In the *Provincial Medical Journal* are reported two cases of complete removal of the patella, and reference is made to three other cases Dr Kummer of Geneva, has reported the following data in the case of a female aged 25 years, with primary tuberculosis of the right patella, but with a perfectly intact knee-joint in which he made excision of the bone with excellent results Two months after the operation, the patient was able to extend her right lower limb as under normal conditions, would kneel with perfect freedom, and without any pain or discomfort Could walk four or five hours daily without lameness or fatigue, or run down staircases with ease, etc In short, the only inconvenience caused by the absence of the knee-cap consisted in a relatively weakened extension of the corresponding limb

"There can be no doubt," says DR KUMMER, "that in suitable cases, a total extirpation of the patella can be performed without impairing the patient's gait, or markedly interfering with movements of the knee joint The operation is indicated in cases of *tubercular osteitis of the patella, provided the articulation remains yet intact* Extirpation can actually prevent the development of articular lesions, and thus save the knee-joint, provided the operation is resorted to sufficiently early In cases of tubercular osteitis of the knee-cap, total removal of the bone offers better chances in regard to recovery than scraping out the morbid foci"

Another successful case is that of DR KAUFMANN, reported in the *Correspondez-Blatt für Schweizer Aerzte* The patient, a married lady, aged 33, was suffering from fungoid osteitis of the left knee-cap, of eight years standing A month after the operation, she, being frightened by a fire next door, tore off all the dressings and ran out of the house, having swiftly descended a staircase Since then her knee-joint has been perfectly movable and her gait normal DR KUMMER mentions two other cases of primary tubercular osteitis of the patella in boys, in which the whole of the bone was removed by PROFESSOR KOCHER of Berne An interesting case of total excision of the patella for acute necrosis has also been published in the *Lancet*, by MR FREDERICK PAGE of Newcastle-on-Tyne The patient recovered, with a perfectly useful limb

THE PATHOLOGY OF IDIOCY

HAMMARBERG ("Clinical and Pathologic Studies concerning Idiocy, with Investigations into the Normal Anatomy of the Brain Cortex," Academic Thesis, Upsala, 1893) who unfortunately died from the effects of appendicitis at the very beginning of a most promising career, reaches the following conclusions after a thorough and elaborate examination of the brain cortex of a number (nine) of idiots in all the cases, which include the principal forms of idiocy, it was possible to explain the psychic defects as due to a lack of cortical nerve cells capable of normal functions

This absence of normal cells was found to be due, either to an arrest of the development of a greater part of the cortex at a stage corresponding to the embryonal, or to that found in early infancy, or to the actual destruction of cells during the growth of the brain In all cases it is made clear that at a certain time the normal development of the cortex became arrested

The degree of idiocy is shown to depend upon the intensity of the acting cause, upon the extent and the functions of the cortex involved, and upon the time at which the arrest in development occurred It is also demonstrated that certain abnormal cell forms as well as peculiarities in the arrangement of the cells in the cortex, which have been regarded as characteristic of the idiot, merit only a secondary importance The essential moment in the production of the psychic defects of idiocy is the lack of cells capable of *function*

In addition to the usual methods, HAMMARBERG relied essentially upon a method of his own, by means of which he was able to determine with exactness the actual number of nerve cells in a cube of brain cortex 0 1 mm in size, and before drawing any conclusions as regards the cortex of idiots, he carefully examined the cell arrangement, number, size and structure in the various layers of the normal cortex Preliminary investigations demonstrated that fixation and hardening in alcohol, cleaning in xylol, and embedding in parafin resulted in the least actual artificial changes which were also constant in different brains and in different parts of the brain cortex The pieces were then cut into serial sections, fastened on the slide and stained with methylene blue according to NISSL's method Counting of the cells in the various layers of the cortex was made by throwing the positive picture of a glass slide ruled into squares upon the preparation under the microscope in such a manner that by means of an objective micrometer each space in the field was made to accurately measure 0 1 mm square The cells present in the same number of squares in ten serial sections, all of which were 10 μ thick, were then counted and the sum, divided by the number of squares counted in each section, would equal the number of cells in a cube of 0 1 mm of cortical substance

NEW REGULATIONS FOR PRACTICE OF DENTISTRY IN NEBRASKA

An almost entirely new law has been passed in Nebraska, regulating the practice of dentistry First of all, it requires that a certificate therefor shall be obtained from the State Board of Health and recorded with the clerk of the county in which the dentist is to practice In the discharge of its duties, in this connection, the board is to be assisted by three secretaries whom it shall appoint from a list recommended by the State Dental Society These secretaries will conduct the examinations provided for, a part at least of which examinations must be in writing and remain in the hands of the secretaries, open to the inspection of any and all persons for one year But a graduate from a reputable dental college or university may, on presentation of his diploma and affidavit that he is the lawful possessor of the name, be given a certificate to practice if he shall, upon investigation of the diploma and affidavit, be found entitled to practice

The term, "reputable dental college or university," is to be defined as dental college or university requiring a preliminary examination for admission of its course of study and which requires as requisite for the granting of a dental degree, attendance on at least three courses of lectures of six months each, no two of said courses to be held within one year, and having a full faculty of professors in all different branches of dental education, to-wit anatomy and oral surgery, physiology, chemistry, materia medica, therapeutics, operative dentistry and prosthetic dentistry and clinical instructions in the last two named *Provided*, that this three year clause shall not apply to degrees granted prior to July, 1892

Any person shall be regarded as practicing dentistry within the meaning of this act, who shall profess to or perform any operation usually considered as belonging to the practice of dentistry *Provided*, that nothing in this act shall be so construed as to prevent physicians or surgeons from extracting teeth *And provided*, that *bona fide* students in dentistry shall be permitted to perform operations under the immediate supervision of their preceptor If, for such operations any fee or compensation be received, either directly or indirectly, then such person shall no longer be considered a student and he or she shall conform to all the provisions of this act

Certificates shall be refused to persons guilty of dishonest and dishonorable conduct, and they may be revoked for like causes But the person must first be given an opportunity to be heard in his or her defense

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION

Among the active, progressive and special associations of this country, the Southern Surgical and Gynecological Association takes a high rank The excellence of its scientific work, year after year, has attracted marked attention both at home and abroad This Association will hold its eighth annual meeting in the Hotel Shoreham, Washington, D C, November 12, 13 and 14, under the presidency of Dr Louis McLane Tiffany, of Baltimore Thirty-seven papers are listed to be read, many of the authors of which are men of national reputation, whose contributions to gynecological and surgical literature have reflected luster upon the profession

The Washington Obstetrical and Gynecological Society will give the Association a banquet on the first evening of its meeting On the evening of November 13, Dr Joseph Taber Johnson will tender the members and their guests a reception at his residence

The Journal of the American Medical Association, as usual, will publish a fair abstract of its proceedings

Dear Doctor —Please direct the attention of your friends to *our* Journal *We will be pleased to send sample copies* to any names you may suggest

CORRESPONDENCE

Ectopic Gestation

Toledo, Ohio, Nov 1, 1895

To the Editor —Dr D von Ott at Petersburg, in Russia, has *recently published his clinical and experimental observations* concerning ectopic pregnancy Of the most importance for the practitioner I consider his thoughts regarding therapeutics, and therefore I wish to lay out his conclusions

Wherever the diagnosis of an uninterrupted extra-uterine gestation is positively made, the extirpation of the ovary by laparotomy is indicated If the patient has reached the second half of pregnancy, we may, if the mother demands it, delay operation until the fetus can be considered able to live, although great dangers are connected with this risk

If pregnancy is advanced to first and second months only, and the further development now stopped, that means if the fetus is dead, we may restrict our therapeutic action to close observation of the patient If gestation is farther advanced and the fetus dead, extirpative treatment is still allowed, although the prognosis is less favorable and although the final cure demands rather a long time A relative indication for operative interference, we therefore find here also, which in general should be preferred Even if the extra uterine pregnancy does not offer any alarming symptoms, as hemorrhage or acute inflammation, which naturally would demand operation, it very often interferes with the welfare and health of the woman Extirpation four to six weeks after death of fetus should be done, if there is no tendency to quick resorption At this time the placental vessels are obliterated, which condition does away with the danger of hemorrhage

If the ovum is not removed, resorption should be favored by massage and electricity, carefully applied

Hematocele, produced by ectopic gestation, should be removed by laparotomy, because this is the only way to satisfactorily remove the condition In case of suppuration and putrefaction, the operation should be made from the vagina

The results of the author are good ones, in twenty one laparotomies one death which is a mortality of 4 8 per cent

B Becker, M D

Pan-American Medical Congress, and the Journal

Colorado, Texas, Oct 30, 1895

To the Editor —I see in Journal just received, notice of "*Transactions of the First Pan-American Medical Congress*" recently published I was a member of the Congress from Texas, and paid $10 dues Am I entitled to copy, because of this fact, or will I have to buy it?

I congratulate you on your signal success in the management of the Journal It is now in every respect the equal of any published, and may you stay with it

Very truly yours,
P C Coleman, Pres T S M A

Answer —The copy reviewed by the Journal was an advance copy sent by President Pepper for notice We have no doubt the members will receive their copies in regular course of distribution Thanks for words of encouragement

A Western Opinion of the Journal

FROM ONE OF THE STATE BOARD MEDICAL EXAMINERS

Denver, Colo, Oct 15, 1895

To the Editor — Let me congratulate you upon the great improvement in our Journal recently I feel sure that its tone comes more nearly meeting the approbation of the part of the profession which it should reach, than if gotten up in more popular "crossroads" style

Yours very truly, J N Hall, M D

BOOK NOTICES

Pioneer Work in Opening the Medical Profession to Women Autobiographical Sketches, by Dr Elizabeth Blackwell Cloth, pp 264 London and New York Longmans, Green & Co 1895

This book is unique, because it is the autobiography of one of the leaders of the movement by which women were admitted to the general medical profession Indeed, we might say the leader, for Dr Blackwell was the first woman admitted as a student to the general classes in medicine, the story of which is told in the appendix to this work in a very interesting manner by Dr Stephen Smith, of New York While women were freely admitted to practice obstetrics and gynecology, as did Louise Burgeois and Madame La Chapelle yet they were kept aloof from general medicine and surgery until the opening in our day to women of medical classes and the establishment of medical colleges exclusively for women The story of her early years while earning money for study and studying in America, takes up the first three chapters Chapter iv is given to the story of her study in Europe, its difficulties and trials Chapter v to her practical work in America Chapter vi, a revisit to England and the return to New York, and the last and seventh chapter her final return to England

As the period of medicine covered in this autobiography from 1821 to 1869 is among the most interesting in the history of medicine, so this book, which gives occasional curious glimpses of interviews with the great men who occupied prominent positions in the earlier half of the century, is full of interest In our day we can hardly imagine the annoyance, not to say insults, that the woman medical student was compelled to submit to in order to gain a medical education, and one can only wonder in reading the book of Dr Blackwell at the patience, the endurance, and the single heartedness which enabled her to complete her course, at the same time, it is seen that among the many rebuffs which were encountered were many pleasant experiences which had, we suppose, a soothing effect under the irritating influences to which she was frequently subjected Now that woman has come into medicine to stay, we trust that she will not forget that the men have practiced medicine and have gained honor and success in its practice, not because they were men but because they were thoroughly equipped in the great principles of an honorable profession, and if women succeed everywhere in this calling it will be in exact proportion as they thoroughly equip themselves for the business, rather than because they are women

One beginning the book is hardly likely to lay it down until it is finished The anecdotes told are interesting, and among them is the following (pp 194 and 195) "My first medical consultation was a curious experience in a severe case of pneumonia in an elderly lady I called in consultation a kind-hearted physician of high standing, who had been present in Cincinnati at the time of my father's fatal illness This gentleman, after seeing the patient, went with me into the parlor There he began to walk up and down the room exclaiming 'This is a most extraordinary case Such a case never happened to me before Really, I do not know what to do' I listened to him with surprise, although he was very much perplexed, as it was a clear case of pneumonia, and had no unusual degree of danger, until I at last discovered that this perplexity related to me, and not to the patient, and the propriety of consulting with a lady physician I was both amused and relieved I at once assured my old acquaintance that it need not be considered in the light of an ordinary consultation, if he were uneasy about it but as a friendly talk Finally, he gave me his best advice, and my patient rapidly got well Happily enough afterward, I had no difficulty in obtaining necessary consultation from the members of the medical profession"

Functional and Organic Diseases of the Stomach By Sidney Martin, M D, F R S F R C P, etc, with 57 illustrations Cloth, 498 pages Edinburgh and London Young J Pentland Philadelphia J B Lippincott Company 1895

The English teachers have always had a high standing as physiologists, and have excelled in it as the Scotch have excelled in pathology, and we have no hesitation in saying that since the famous books of Thomas King Chambers, no book dealing with stomach digestion and its derangements and the lesions of the organ itself has been more complete or more thorough in its treatment of the subject The typographical execution of the work is excellent, and the illustrations are all good, and some of them very fine The book is divided into sixteen chapters, as follow i Anatomy and Physiology of the Stomach, ii, Digestibility of Various Articles of Diet and the Effect on Digestion of Food Exercise, as Condiments, Alcoholic Drinks, Tea, etc, iii, Pathology of Indigestion of Food, iv, Pathology of Indigestion of Food Continued, v, Methods of Examination of the Functions of the Stomach in Disease, vi, Symptoms Referable to Indigestions of Food with or without Anatomic Changes in the Walls of the Stomach, vii, Functional Disorders of the Stomach, viii, Mechanical and Active Congestion of the Stomach, Gastritis, Gastric Catarrh, ix, Gastritis Toxica, Gastritis Mycodica, Atrophy and Degeneration of the Stomach, x, Treatment of Acute and Chronic Affections of the Stomach, xi, Treatment of Acute and Chronic Affections of the Stomach Continued, xii, The Same Continued, xiii, Bleeding from the Stomach, Hematemesis, xiv, Dilatation of the Stomach, Cirrhosis Ventriculi, xv, Ulcer of the Stomach, Acute and Chronic, xvi, Cancer of the Stomach

While the treatment by electricity and hygienic measures are noted, nothing whatever is said of the operative treatment in cases of carcinoma or tumors of the stomach, the work being confined to the medical aspects of the subject

Text-book on Forensic Medicine and Toxicology By Arthur B Luff, M D, B Sc, London Lecturer on Medical Jurisprudence and Toxicology, St Mary's Hospital, Examiner in Forensic Medicine, University of London, External Examiner of Forensic Medicine in the Victoria University, Official Analyst to the Home Office London and New York Longmans, Green & Co 1895 The work consists of two volumes, pp 416 and 360 respectively

This work has been written as a text-book for students of medicine, and as a work of reference for practitioners in connection with medico legal cases Special reference is given to toxicology There are twelve full-paged plates and twenty-four illustrations in connection with the toxicologic branch of the subject The contents of the volume are as follow Chapter i, Medical Evidence, Importance of Knowledge of Medical Jurisprudence, Dying Declarations, Procedures in Magistrate's Court, Coroner's Court, Court of Assize, Attendance of Witnesses, Common and Expert Witnesses, etc Chapters ii, iii, iv, v, vi and vii are devoted to questions connected with the dead body Chapter viii, the general subject of toxicology, and ix, x, xi, xii and xiii to inorganic poisons, Chapters xiv, xv, xvi, xvii xviii, xix, xx, xxi, xxii, xxiii and xxiv to organic poisons The book is well printed and the illustrations are excellent The tests given are those recommended in the latest works on chemistry, and many of the procedures are drawn from the personal experience of the author In examining the book we are inclined to think that the portion relating to toxicology would be of most interest to the American profession, as the procedures of the English courts differ in many important respects from those prevailing in this country However, the general principles of the English common law prevail in this country in the absence of any statutory provision We commend the work suited to practice Dr Ransom gives details of his experiments in which he obtained from virulent cholera cultures a fluid free from bacteria and equally fatal to guinea pigs, and then a dry, stable substance having the same power Then guinea pigs, etc, were treated according to known methods of immunization to obtain an antitoxin Serum from these animals was found to afford protection to guinea pigs receiving injections of the cholera toxin, even when the dose was made three times the ordinary fatal amount, and alike whether the dry toxin, the clear solution from cultures or the living vibrios were used, and even when the toxin was used 48 hours after the antitoxin Dr Ransom gives a resumé of his researches as follows 1, it is possible to obtain a cholera culture fluid, free from bacteria, which shows specific qualities, 2, the post mortem appearances which result from this fluid are similar to those which follow the use of living cholera vibrios, 3, from this fluid can be obtained a stable substance the action of which is identical with that of the original fluid, 4, from animals susceptible to cholera, which have been treated with cholera toxin, a serum can be obtained, which proves to be equally effective against cholera toxin and against the living cholera vibrios —*Deutsche Medicinische Wochenschrift*, July 18, 1895

Congenital Syphilis and Tuberculosis —Hochsinger (*Wiener Med Blatter*, 1894, Nos 20 and 21), concludes that syphilis and tuberculosis can appear as a mixed infection at the earliest possible age, and that this infection may be congenital This conclusion is based on the clinical and anatomic investigation of three cases The first child born of a syphilitic father and a tuberculous mother died on the thirty-first day During life an undoubted syphilitic cutaneous eruption existed, and a simultaneous pneumonia with enlargement of the spleen and the liver led to the diagnosis of syphilis The post-mortem examination showed an extensively distributed tuberculosis of the internal organs with large and caseous nodules that contained the tubercle bacilli The second case concerned a child that died on the thirty eighth day The history, the syphilitic eruption, and a pneumonia seemed to warrant the diagnosis of syphilis The lung was the only tuberculous organ in this case The third case presented pronounced syphilitic lesions and died during the sixteenth week from pneumonia The section showed a chronic tuberculous broncho-pneumonia, tuberculosis of the spleen, of the lymph glands and interstitial syphilitic hepatitis without tuberculosis of the liver Hochsinger regards such cases as not uncommon and lays stress upon the necessity of examining the contents of the nodules for bacilli, in order to determine whether syphilis or tuberculosis is present The question whether the tuberculosis was congenital or acquired in these cases can not be determined in Cases 2 and 3 Of the first case it may be said with certainty, however, that the syphilis was the result of a spermatic or paternal infection and that the tuberculosis was due to a placental infection, because the caseous masses with tubercle bacilli in the liver speak in favor of infection through the umbilical vein

Goitre Among the Indians of the United States —First Lieutenant and Assistant Surgeon Munson, U S Army, contributes an interesting and timely article concerning the prevalence of goitre among certain Indian tribes[1] Munson obtained a great deal of information in regard to this subject by means of a series of questions sent to the physicians of the sixty-three agencies of the Indian service, all of whom responded except three It was found that the number of Indians located on reservations from which goitre was reported amounted to 77,173, and that among this number there were 1,823 cases of bronchocele or about 2 36 per cent, taking into consideration the population of all the reservations from which positive as well as negative reports were received the percentage would be 1 23 As regards geographic distribution the disease is most prevalent in the southern part of Montana There seems to be no question but that racial predisposition to goitre is illustrated by the Indians because the disease was reported as practically unknown among the white settlers living in or about the reservations where goitre was prevalent among the Indians It seems also that fully 80 per cent of the cases occur in Indian females, the disease being not only much less frequent but also less rapid and less extensive in the male The average age for the disease to begin was found to be at from 12 to 14 years Nearly every report gives instances illustrating the apparent heredity of goitre and many instances are cited in which several consecutive generations showed its development It is very interesting to observe that only one case is reported in which goitre was associated with cretinism The following are some of the other salient points of this article goitre among the Indians can not be traced to high altitude, climate or water containing an excess of calcium salts, the disease is undoubtedly caused by unsanitary surroundings, depressing constitutional conditions, and an improper and excessively nitrogenous diet, the tumor is apparently smaller than the one usually observed in whites, the usual treatment is not satisfactory

The Diagnosis of Syphilomata —How are syphilitic sarcomata and lymphomata to be distinguished anatomically and clinically from other sarcomata and lymphomata? (v Esmarch at the Twenty-fourth Congress of the German Society for Surgery, April, 1895) It is a well-known fact that tumors often appear, which are due to constitutional (acquired or inherited) syphilis and which disappear after appropriate internal treatment, but since they can be easily mistaken for other malignant tumors (sarcomata, carcinomata), they often lead to unnecessary operations In his own practice more than forty cases had appeared, in which tumors, at first regarded as malignant sarcomata or carcinomata, were shown to be undoubted syphilomata And he has found a far larger number in print, which, in the light of his present experience, he might stamp as suspicious In this light he would regard 1, all cases of tumors in patients who showed at any other time symptoms of syphilis, or where the history showed that their parents or brothers or sisters had had syphilis, 2, all tumors, resembling sarcomata, which develop in voluntary muscles, especially in the sterno-mastoid, in the muscles of the abdomen, the back and the lower extremities, also the tongue, 3, all sarcomata, which, after complete extirpation, recur at first slowly, then after shorter and shorter periods (recurring fibroids, Paget), 4, all tumors, which diminish or disappear after use of iodid of potash, mercury and arsenic, 5, those sarcomata which disappear after attacks of erysipelas or after injections of the toxins of erysipelas, etc All these grounds for suspicion are strong points in the clinical diagnosis, and the more of these coexist in a given case, the more probable it is that the tumor is of syphilitic origin, the more cautious must the surgeon be, before he determines upon an operation, the more searching must be the examination of the whole body and of the clinical history In this way it is not rarely that one finds a clue (eruption, ulcers, cicatrices, teeth, eyes, etc) The external appearance of the tumors and the manner and duration of their growth are so varied that no diagnostic signs can be drawn as a rule From the anatomic appearance (after extirpation, or removal of a portion) a diagnosis can at times be made at a glance, if one finds in the section the strikingly mottled picture which Virchow has so excellently described The microscope also discloses much of value, especially negatively But in many cases syphilomata can not be distinguished, macroscopically or by the microscope, from small-celled and spindle celled sarcomata The same is true of exuberant granulomata which sometimes arise from broken-down gummata But the greatest difficulties in diagnosis are seen in syphilitic lymphomata, which appear, especially as a late symptom, in inherited syphilis, and which are often confounded with tuberculous or pseudo-leucomatous, malignant lymphomata and lymphosarcomata Syphilomata arise also in other glands, especially in the mamma, testis and salivary glands, and are generally not recognized before extirpation Inasmuch as all these tumors recur after increasingly shorter periods, until the patients at last succumb, it would be of inestimable value to us, if we had some means, at least by the microscope, of deciding whether the tumor was due to syphilis or not That we have to do with bacilli or similar organisms (protozoa) in syphilis we feel reasonably sure from the manner of infection and the whole course of the disease But unfortunately the labors of investigators, from Lustgarten to Döhle, have not succeeded in establishing beyond doubt that the microörganisms found are the cause of the infection or are present in all products of syphilis —*Centralblatt für Chirurgie*, July 6, 1895

---

[1] New York Medical Journal, Oct 26, 1895

The Pathologic Anatomy of Progressive Muscular Atrophy —Cramer, of Gottingen, presents a thorough review of the literature of the anatomic changes in the various forms of progressive muscular atrophy (*Centralblatt fur Allgemeine Pathologie u Pathologische Anatomie*, vi Band, No 14–15) He divides all the cases into the following groups 1, cases without any changes in the central or peripheral nervous system, 2, cases with changes in the peripheral nerves only, 3, cases presenting lesions in the spinal cord, 4, cases with alterations in the brain and he gives tables embodying the essential facts recorded concerning all the reliable and complete cases of each group published in the literature

His final conclusions after a careful consideration of all the instances are the following 1, there are muscular atrophies in which the present means of investigation fail to disclose any lesions whatsoever in the central or peripheral nervous system, even after the atrophy has existed for ten or twenty years These atrophies correspond clinically to some one of the forms which Erb includes under the name of dystrophy, 2, the muscular atrophies that develop in connection with demonstrable spinal affections present many different clinical pictures The same complexus of symptoms which is characteristic of dystrophy, as well as typical spinal muscular atrophy may develop in conjunction with the same spinal lesion Even an isolated disease of the ganglion cells in the anterior horns may give rise to such widely differing clinical manifestations *A special lesion may consequently* be present in cases of dystrophy or the peripheral and central nervous system may be found intact, 3, there are found transition forms between the cases without central or peripheral lesions and those with spinal affection, as well as between the so-called spinal muscular atrophies and the atrophies that develop in connection with other diseases of the spinal cord, 4, the changes in the muscles themselves are practically and, on the whole, identical in the atrophies with spinal cord lesions and in the myopathies without central changes The microscopic changes in the muscles present nothing that is characteristic of any single form of the disease, 5, the pathogenesis of muscular atrophy is not clearly understood. It appears, however, that an embryonal disposition that may become hereditary must be taken into consideration as an etiologic factor Whether this supposed pathogenic factor that comes into play in embryonal life attacks the nervous system or the musculature directly has not been determined, 6, there are cases of muscular atrophy with an isolated disease of the peripheral nerves which seem to assume an especial type (the neural form of Hoffmann) The muscular changes in this form do not present any essential differences from those of the two other kinds of atrophy mentioned, 7, the muscular atrophies of locomotor ataxia show some similarity to the neural form, 8, there are muscular atrophies dependent upon central lesions which mostly consist of focal changes in the region of the central convolutions Such muscular atrophies can develop without any visible morbid changes in the pyramidal tracts or in the ganglion cells of the anterior horns

Treatment of Eclampsia —By Prof Dr A v Gurbaroff, of Jurjew (Dorpat) Since the treatment of eclampsia even to day scarcely permits us to expect favorable results, inasmuch as the death rate for the mother is placed at 25 per cent (Auvard) or even 30 per cent (Ahlfeld), the following observations on the six cases of this severe complication, which have been observed since my entrance into the woman's clinic in this city, seem to me to be not without practical interest, since all these cases terminated favorably for the mother This would lead us to assume a mortality of zero, and I scarcely think it could be shown that the result obtained did not depend upon the treatment Of the six cases, three presented very severe phenomena, as very *high and long continued temperature, protracted comatose* condition, large amount of albumin in the urine, frequent convulsions, etc The treatment was as follows administration of narcotics, principally morphin, in moderate but repeated doses (015 gm subcutaneously about six times in twenty-four hours according to the quantity of urine), enemata of chloral and only during operative maneuvers (including catheterization of the bladder) light chloroform narcosis All external means which could stimulate or supply vicariously the activity of the skin, were applied freely Among these, warm baths only very seldom, moist, warm coverings always, further, many times a day, rubbing with warm vinegar-salt-alcohol solution and simple supplying of heated air In all cases, attention was given as early as possible to securing thorough emptying of the intestines by salines (sodium and magnesium sulphates, āā) Beside, in all cases, great attention was bestowed on the function of the kidneys This was stimulated by the administration of milk and certain mineral waters, and by application of local heat to the region of the kidneys by means of a large hot water bag, which always exerted a remarkably favorable influence on the secretion of urine Especially in the three severest cases, in which there was entire loss of consciousness, coma, with high temperature (39, 40 degrees C), and greatly diminished secretion of urine, the quantity of urine was strikingly increased and the albumin much diminished, coincidently the general condition began to improve and recovery followed after a few days This result appears to me so exceptional, that I feel justified in recommending strongly the continued local application of heat over the loins, especially in cases in which there is much albumin and markedly diminished secretion of urine Venesection was employed in only one of these cases In this case convulsions began at the end of the seventh month and were very severe The patient was brought into the clinic in a deplorable condition The eclamptic seizures followed one another rapidly and in the intervals the patient was wholly unconscious Temperature 38 to 39 degrees, pulse 90 to 112 The os admitted one and one-half fingers, no contractions of the uterus Abortion was produced Barnes' dilators were introduced and after four hours the sac was ruptured and a dead child was delivered with forceps The convulsions continued Pulse 90, strong, respiration labored and stertorous Unconsciousness persisted After eight hours 600 gms of blood were drawn from the left median cephalic vein The paroxysms suddenly ceased, respiration improved, there was an increase in the urine and marked diminution in the albumin Temperature before venesection 38 5 degrees, pulse 76, shortly after 37 8 degrees, pulse 80 On the next day 500 gms more of blood were drawn Soon after the patient became perfectly conscious Albumin disappeared from the urine On the fifth day symptoms of puerperal mania were manifested, joined with rise of temperature, but these soon passed away —*Centralblatt für Gynakologie*, No 5, Feb 2, 1895

The General Therapeutic Effect of the Alternative Electric Current of High Frequency and of High Tension —Dr Apostoli, together with Dr Berlioz, on March 18 1895, presented a paper on the above mentioned subject to the Academy of Sciences of Paris He now, after longer and riper experience, desires to present a summary statement of his general conclusions

1 *According to Professor d'Arsonval's discoveries*, alternative currents of high frequency and of high tension, exert a powerful action upon all living bodies submitted to their inductive influence

2 The best method of applying these induced currents is to place the patient, free from all contact with electrodes, in the circuit of a large solenoïd traversed by these currents The patient being thus completely insulated, the currents which circulate in his body by auto-conduction, have their origin in his tissues The body plays the role of a closed induced circuit

3 By this method the physiologic discoveries of Professor d'Arsonval are confirmed and we are able to prove the powerful influence of these currents upon the vasomotor system—although they produce absolutely no sensation and although they have no apparent effect upon the motor or sensory nerves These currents have nevertheless a powerful action upon all the nutritive functions, as has been verified by Dr d'Arsonval's numerous analyses of the gaseous

products of respiration and by Dr Berlioz's not less numerous analyses of the urinary excreta

4 The general therapeutic applications to be deduced from this physiologic action are confirmed by clinical observation Dr Apostoli has now treated more than a hundred patients by this method at his clinic and at his private consultation rooms The greater number of these patients have been greatly benefited by this new treatment, which, be it remarked, has been used to the exclusion of all other forms of medication, dietetic or otherwise

5 The currents exert in the majority of cases a most powerful and generally beneficial action upon diseases due to slackening of the nutrition, by accelerating organic exchanges and combustion This is proved by analyses of the urine made by Dr Berlioz, of which the following is a brief resumé

The quantity becomes more normal, the products of organic waste are better eliminated The increased combustion is shown by the diminution of uric acid, while the percentage of urea is generally increased The relative proportion of these two substances changes under treatment so as to reach in general the figure of 1–10 The elimination of the mineral products is also changed, but in a manner less marked.

6 When daily séances are given, each lasting fifteen minutes, we may generally observe in patients submitted to the influence of these currents the following modifications in their general condition We mention them in the order of their occurrence return of sleep Increase of strength and vital energy Increase of gaiety, of power for work and ability to walk Improvement of appetite, etc In short, general progressive improvement This general improvement often manifests itself after the first séances before any local influence is apparent and before any change has occurred in the urinary secretions

7 Local pain and trophic changes are often more slowly affected by these currents and at times they are entirely refractory for a longer or shorter period In such cases the same currents must be applied locally by contact with the electrodes This subject will be treated later on in a separate communication

8 The diseases which have appeared incurable by this treatment are those not associated with well defined organic changes such as hysteria and certain forms of neurasthenia Dr Apostoli has also observed that certain localized neuralgias are refractory to this form of currents, they require its more direct local application

9 The diseases which have derived most benefit from this therapeutic agent, belong to the arthritic class rheumatism and gout

10 In certain diabetic subjects the sugar has disappeared altogether from the urine under the influence of these currents, while in others there has been no such change, notwithstanding the manifest and constant improvement in the general condition Is this difference due to the imperfection of the electric apparatus or to the manner of its application? It is hoped that further experience will soon afford an answer to this question, although the fact that diabetes has many different causes, may in itself explain the difference in the results obtained by this treatment

In conclusion, the currents of high frequency and of high tension introduced into electro-therapeutics by Dr d'Arsonval greatly increase the field of action of medical electricity They furnish general medicine with a new and valuable means of treatment, capable of modifying more or less profoundly the processes of nutrition—(Abstract of a paper read before British Medical Association, 1895)

PUBLIC HEALTH

Typhoid Fever—In Connecticut, New York, Pennsylvania, Ohio, Michigan, District of Columbia and Chicago, typhoid fever has been unusually prevalent It is probable that in Pittsburg and Allegheny the disease has been more severe according to population than most of the other cities With the advent of cold weather, however, the disease will become less serious, and in Chicago it has already markedly diminished

To Regulate Undertaking—A law has been passed in Pennsylvania to provide for the better protection of life and health by diminishing the danger from infectious and contagious diseases through the creation of a State board of undertakers in the cities of the first, second and third classes, with systematic examinations, registrations, and licenses for all entering the business of burying the dead With the exception of a special provision made for persons now engaged in the business of undertaking, applicants for licenses must be examined by the board and found to be possessed of good moral character, skill and knowledge of the business of undertaking and have a reasonable knowledge of sanitation, preservation of the dead, disinfecting the body of deceased persons, the apartment, clothing and bedding in case of death from infection or contagious diseases All persons receiving a license from the State board of undertakers, shall also register the fact at the office of the board of health at the city in which it is proposed to carry on business But nothing contained in this law is to be construed to apply to *bona fide* employes of a duly licensed or registered undertaker, or to persons engaged simply as layers out or shrouders of the dead, or to the employes of any cemetery whose duties and business extend no further

Pasteurization of Milk and Cream for Direct Consumption—Bulletin No 44 from the Agricultural Experiment Station connected with the University of Wisconsin, consists of a scientific as well as practical dissertation upon the pasteurization of milk and cream, written by H L Russel, and the following conclusions are of direct interest to the physician as well as to the layman from a hygienic point of view the elimination of living germs from milk is imperative At present, no better methods have been suggested for this purpose than pasteurization and sterilization Inasmuch as pasteurized milk and cream conform more closely to the normal fresh product in certain essential particulars than the sterilized, it follows that pasteurization is better adapted for general purposes The pasteurization of milk or cream consists in heating the liquid to a temperature that is fatal to the vegetating growing bacteria and still not high enough to materially change the physical characteristics of the product The minimum limit for pasteurizing should be a point at which the tubercle bacillus is killed, and in general an application of heat at 155 degrees F for twenty minutes may be chosen as a medium standard Treated in this way, and chilled as quickly as possible after the heating, the destruction of germ life in the milk averages about 99 7 per cent, and the effect of stopping the putrefaction and fermentative processes of so much organic life can not be attended with other than beneficial results

Tuberculosis in Cattle and the Tuberculin Test—The close relation between bovine tuberculosis and certain forms of human tuberculosis render all scientific investigations into the condition of dairy cows as regards the existence of tuberculosis of great interest to the physician, to say nothing about the great practical importance of such studies In Bulletin No 40 of the Agricultural Experiment Station of the University of Wisconsin (issued July, 1894) are contained the details of results obtained with the injection of tuberculin in the station herd consisting mostly of milch cows, and at this time it will suffice to say that of the thirty animals inoculated, twenty two responded or reacted to the test in such a positive manner that there could be no question as to the diagnosis, and this diagnosis was verified in every instance by the post-mortem examination, showing that in this herd there existed a veritable epidemic of tuberculosis Russel, the bacteriologist to the station, and the author of this bulletin, concludes with the following recommendations as regards the use of tuberculin 1, that it be employed in herds used for a general milk supply, because here is the main source of danger as regards human infection from the use of milk containing tubercle bacilli In connection with this, the question becomes pertinent as to how many milkmen supplying large cities, or smaller for that matter, are ready to furnish a guarantee to their patrons, based on the use of the tuberculin test, that there is no possible chance of disease lurking in the herds furnishing the milk 2, in dairies producing milk intended for children and invalids, the necessity for the fulfillment of this recommendation needs no emphasis from the physician who knows only too well the great susceptibility of the immature system of the child, or of the enfeebled one of the invalid to tuberculosis, and yet how long shall we continue to prescribe a milk diet without any guarantee of the purity of the milk? This demand can now be met with comparative ease by the dairyman and the consuming public need but say the word that will make it imperative for him to furnish the requisite guarantee 3, in the purchase of new animals the tuberculin test should be passed successfully by the animal in question The justice of this recommendation is self-evident from whatever standpoint taken, and it is particularly the duty of the family physician to see to it that this demand is fulfilled whenever cows are purchased by any of his patrons for the purpose of supplying children or invalids with absolutely pure milk It is quite plain that if the demands for non-tuberculous milk were carried to the extent included in these recommendations, then tuberculosis among cattle would be almost entirely stamped out in the course of time, and it would seem the plain duty of local health departments and of the State Boards of Health to take an active part in educating the public and the medical profession up to a point where the importance of this comparatively simple method of preventing tuberculosis would be fully understood and enforced—by direct legislative means, if necessary

Health Reports —The following health reports have been received by the Supervising Surgeon General, Marine-Hospital Service

SMALLPOX—UNITED STATES

New Orleans October 19 to 26, 18 cases, 3 deaths
Michigan, Detroit October 19 to 26, smallpox reported Rochester, October 19 to 26, smallpox reported, Hamburg Twp, October 23, 1 case

SMALLPOX—FOREIGN

Buda Pesth October 7 to 14, 1 case
Cairo October 1 to 7, 3 deaths
Calcutta September 14 to 21, 1 death
Madrid October 8 to 15, 7 deaths
Moscow September 28 to October 5, 1 case
Naples October 12 to 19, 7 cases, 7 deaths
Nogales October 19 to 26, 1 case
Odessa October 5 to 12, 1 death
Rotterdam October 12 to 19, 1 case
Zurich October 5 to 12 3 cases
Manzanillo September 1 to 30, 17 deaths
England, London October 12 to 19, 1 death
Dublin October 12 to 19, 2 cases

CHOLERA

Bombay September 24 to October 1, 1 death
Calcutta September 7 to 21, 28 deaths
Madras September 21 to 27, 1 death
Singapore September 13 to 17, 2 deaths
Austria-Hungary October 1 to 7, 19 cases, 18 deaths
Russia, Dept of Volhynia September 15 to 28 4,269 cases, 1,701 deaths, Dept of Kew September 19 to 26, 14 cases, 18 deaths
Turkey Constantinople, September 24 to 26, 4 cases, 4 deaths, Hudauendkjar September 20 to 29 9 cases 5 deaths, Diabekir September 12 to 26, 21 cases, 18 deaths, Maschuk September 25 to 28, 10 cases, 6 deaths Mossoul September 20 to 24, 1 case, 2 deaths
Formosa July 28 to August 10, 150 cases, 56 deaths
Tangier September 23 to October 2, 197 cases 142 deaths
Japan from outbreak to October 3, 50,431 cases, 34,719 deaths

YELLOW FEVER

Cienfuegos October 14 to 27, 2 deaths
Sagua la Grande October 12 to 26 10 cases, 1 death
Santiago de Cuba October 13 to 26 50 deaths
Vera Cruz October 17 to 24 1 death
Taribacoa September 1 to 30, 18 cases

ASSOCIATION NEWS

Treasurer's Notice —The Treasurer has received the following for membership dues with which names were not sent

$5 (currency) Envelope post marked Boston, October 27, 10 P M

$5 (currency) wrapped in piece of purple paper Envelope post-marked Los Angeles, Cal, October 30, 1 30 P M

$5 check not signed No 71, Cincinnati, Ohio, on the National LaFayette Bank

Any information in regard to the above will be appreciated by the Treasurer, H P Newman, Venetian Building, Chicago

MISCELLANY

Protonuclein —Protonuclein is the last of the many substances which is recommended as "a positive and never failing" cure for cancer

Correction —In our issue of October 26, in mentioning the Case Recorder of Dr Lyon, his address was given as Milwaukee It should have been 921 Milwaukee Avenue, Chicago

Antitoxin is Vaccine Virus —The second definition given by the Century Dictionary for "vaccine virus" is "In a general sense, the modified virus of any specific disease introduced into the body by inoculation, with a view to prevent or mitigate a threatened attack of that disease or to confer immunity against subsequent attacks" Adopting this meaning of the term, the Board of the United States General Appraisers at New York, decided July 23, 1895, that antitoxin is vaccine virus and as such is exempt from duty under paragraph 664, act of August 28 1894

Heredity in Longevity —The *Dublin Journal of Medical Science* quotes an interesting statement by Sir Benjamin W Richardson concerning his observations on the duration of life of the offspring as compared with that of the parents He considers that if the ages of the two parents and of the four grand-parents be added together and divided by six, the age of the case in point will be told with an average variation of not more than two If the ages of the parents are high, the offspring tends to improve on them, if low (say an average of 40 or lower), the life of the offspring will probably be shorter

The Hahnemann Monument —The *Medical Century* (homeop) says that the sculptor, Mr Chas Niehaus of Pittsburg, has the final model of the Hahnemann statue under way and concludes thus "In this connection it may not be amiss for us to take a little unction unto ourselves because of the success attending our endeavors as monument builders The Allopathic Association, which is also negotiating with Mr Niehaus for the Rush monument, has raised $5,000 in two years for their monument The homeopathists have raised $25,000 in less than a year" We presume our erring contemporary by the term "Allopathic Association" intends to refer to the AMERICAN MEDICAL ASSOCIATION, and although we reject the epithet 'allopathic," we must admit the truth of the remainder of the statement

Treatment Provided for North Dakota Drunkards —There are several provisions in the law passed by the last Legislature of North Dakota which distinguish it from the enactments of some of the other States on the same subject Here it is provided that the drunkard is to be sent to a reputable institute designated by a committee of three persons to be appointed by the Governor *Section 11 of the Act says that* it must be some reputable institute for the treatment of such disease, that will treat the same at the lowest figure, but the board of county commissioners shall not be compelled to send him to the institute making the lowest bid unless, in their judgment, the best interest of the drunkard shall be promoted thereby Furthermore, his cure and treatment is at all times to be under the supervision of the board of county commissioners, who may at any time they see proper, stop the treatment of any such drunkard, or change him from one institute to another, as to them shall seem meet and proper

Memorial Hospital, Brooklyn —On October 30, a new hospital was opened in Brooklyn, the central building and one wing being built and in readiness to take up the work that has hitherto been carried on at 1153 Pacific Street, at a cost of $100,000 According to the plans of the architect, the hospital, when complete will have another wing The present completed structure has accommodations for the three departments of the institution—the hospital proper, the training school for nurses, and the memorial dispensary There are accommodations for 100 patients and 40 nurses The branch dispensary on Bedford Avenue will be maintained as heretofore From seven hundred to one thousand patients are treated there monthly The Memorial Hospital for Women and Children was founded in 1883 The plot of ground owned by the hospital comprises an area of not less than 26,000 square feet, in a very eligible location

Invalid Aid Society of New Mexico —According to the *Albuquerque* (New Mexico) *Citizen*, of October 25, the following petition is being circulated for signatures throughout the United States, at the instance of the Invalid Aid Society of New Mexico

To the Honorable, the Senate and the House of Representatives of the United States

The undersigned, residents of the State of ——, interested in the welfare of the vast numbers who are suffering from pulmonary diseases and other climatic ills in the United States, and believing that the climate of New Mexico is admirably adapted for the alleviation and cure of diseases of the air passages and lungs, respectfully petition your honorable bodies to set aside one or more tracts of land recognized as adapted to such uses, containing 10,000 acres each, to be used as homes and resorts for the benefit of such invalids, the provision for such donation to be incorporated in the bill for the admission of New Mexico as a State

A Series of Ten Thousand Cases of the Serumtherapy of Diphtheria —The New York *Herald's* European edition publishes deductions drawn from statistics collected by a Berlin physician, Dr A Eulenberg, of diphtheria cases treated with antidiphtheritic serum between Oct 1, 1894, and March 31, 1895 in private practice "Out of 10,240 cases of diphtheria reported to him, 5,790 were treated by the antitoxic serum, and 4,450 by other methods The report says that of the 5,790 that formed the first group 552 died—that is to say, 9 5 per cent, of the 4,450 patients of the second group 652 died —that is to say, 14 6 per cent The compiler is of opinion, however, that the cases treated by serum were mostly bad cases of diphtheria, while those treated by the other methods were not so serious This inference is rather confirmed by the report of Dr Kurth, of Bremen, who had only 6 8 per cent of deaths among patients treated by serum, but 24 per cent of deaths among the others" Dr Eulenberg's statistics show also that the efficacy of the serum treatment is greater when it is begun in the very early stage of the diphtheritic attack Thus the total death rate among the patients with whom the serum treatment was begun on the first or second day of the attack was only 4.2 per cent, whereas among patients who did not receive an injection of serum until the third day of the complaint, or even later, the death rate was four times as large (16 8 per cent) In cases of children less than 2 years old, the relative difference in the figures is still marked In the *Deutsche Medicinische Wochenschrift*, for September 19, appears Dr Behring's last paper on the progress of serum treatment, entitled, "*Leistungen und Zeile der Serumtherapie*"

Bicycle Fatigue Utilized —According to the *New York Medical Journal*, an Italian specialist in otology has undertaken the study of the influence of fatigue on audition He made examinations of twenty-four bicycle riders after they had ridden thirty-two miles in two hours and a quarter Two of the men complained of subjective noises only, while in nearly all of them the perception of sound by aerial conduction was less marked than in the normal condition, and the experiment showed negative result In the riders who were subjected to an examination with tuning-forks, a slight diminution in the perception of loud sounds was ascertained The competitors were again examined after a rest of from two to seven hours, and in six of them the auditory powers were found to be the same, in two it was not so good, and in the sixteen others it was better, the aerial perception had increased from a few centimeters to a meter and a half The men in whom the amelioration was most marked, in whom, consequently, the hearing had undergone the greatest change, were those who had had little experience or training Conclusions physical fatigue evidently causes a temporary weakening of the auditory power This fact demonstrates also that the effects produced by great physical exercise are not shown by muscular fatigue only, but they remotely affect the entire organism, and especially the nervous system, while the special senses, on account of the delicacy of their function, are more likely to reveal the effects

The Dishonest Nurse a Rarity —An instance of that rare form of culprit—the thievish nurse—has recently been brought to light in Brooklyn From the editorial page of the *Eagle* of that city the following comments on the case are selected

"Ethel Oliver, a good looking damsel of 22 years, had made a confession Sne has been a nurse in the Seney Hospital, and in that capacity had used her opportunities to steal She robbed the hospital, she robbed her fellow nurses, she robbed the patients, even as they were dying, and she entered the dead-house to despoil the corpses She was so rosy and innocent in her appearance that nobody thought of suspecting her If there is any foundation for believing that a habit of stealing can be a disease, surely this instance seems to support it There was no urgent need for theft The young woman was making fair wages, she had clothing and board and shelter, some comforts and even luxuries She had none of the usual motives that are urged in extenuation of this mean form of crime"

The incident is a sad one and would be an unsettling one, were it not for the fact that such events are of the rarest, it is one of those cases that prove the contrary rule In hospitals, asylums and in private homes thousands of men and women are employed as nurses, and not one in a thousand is known to violate his or her trust The advantages for theft are uncommonly ample The people who may be robbed are helpless, and some are out of their wits, so that they would not know whether they were robbed or not There are no watchers to oversee the nurses and report on their conduct They are in a position of absolute power, for the nonce Yet they almost never presume upon their position and power

Medical Men in Politics —The *Boston Medical and Surgical Journal* comments upon the slender influence over wholesome legislation that comes within the power of the medical profession Doubtless every community has its quota of physicians who are not too much occupied with professional work to give a share of their time to political interests Doubtless, also, a small proportion is willing to engage in legislative duty if called upon so to do by the community wherein they respectively dwell But it is unfortunately, also, the case that those who "go to the front," from our profession, for such legislative functions are not from the representative men in medicine, they are ordinarily chosen to represent something bearing upon "spoils" or "bone-hunting" Their interests with the sanitary and medical interests of their constituents are commonly subordinated to relatively small issues Then, as the *Journal* remarks, the kind of work that is called "political" is, for the most part, distasteful to men of the type who make a success in medical life, and may even be by them regarded as incompatible with professional success The *Journal* closes its article by citing an instance which speaks for itself, regarding the kind of selection of a politico medical representative, that may sometimes be made even in enlightened New England

'A conspicuous example of the influence of the medical man in politics in retarding legislation for the benefit of the public health, was the attitude taken by Senator Gallinger, of New Hampshire, who had been a medical practitioner in that State, on the bill appropriating money for a bacteriologic laboratory and disinfecting service and for the distribution of antitoxin in the District of Columbia It will be remembered that his attitude, as noted in our issue of Feb 7, 1895 was against the passage of the bill, and that his influence was thrown squarely against this legislation for the public health rather than in favor of it There can be no doubt that there is need of the representation of the medical profession in our Legislatures by the right class of men from the highest ranks of the profession And inasmuch as active participation in legislative work is impossible for the rank and file of the profession it becomes the duty and privilege of what may be called the medical leisure class to do this work, we mean those of independent means, who are not dependent upon the practice of their profession for their living"

Senator Gallinger is supposed to be a homeopath and his actions must be viewed from that standpoint

The Medical College of To-day—The Boston *Medical and Surgical Journal*, September 26, prints Dr H O Marcy's address before the Syracuse University Medical Department in June last Dr Marcy's subject was 'Personal Service as the Especial Exponent of a Great Profession" One of the consequents of this Commencement anniversary, was the raising of a fund of $100,000, contributed largely through the instrumentality of the alumni of the University, to be devoted to the erection of a new building, which is already rapidly approaching completion Of the old and the new in medical colleges, he spoke as follows

"The medical college of to day demands another building or a series of buildings, than that of the former pattern The amphitheater as the lecture room—cramped crowded, stifled in the upper rows, to the last degree inconvenient of access, reached by garret stairs, to descend to seats, as upon an illy-constructed ladder, a nightmare dream of our earlier years—should be relegated to the past Bright, airy, well lighted rooms are required, made pleasing and attractive, with good seats and tables, where the personal work may go on under the direction of well-trained assistants The modern medical college should be so closely connected with the hospital that the clinical teachings may be made illustrative and profitable Indeed, the hospital should be the *workshop* in the better sense, where the student becomes familiar with the 'living pictures' of our poor broken humanity, the reconstruction of which is to be his future life-long labor Hospitals are important for the care, especially of the poor the home for the friendless These, the public have long held in kindly interest and support As a rule, the best physicians of the respective localities have willingly rendered gratuitous service, but the medical college has been too often looked upon as a private affair, a doctor's business venture, entered into for gain Should it not, the rather, be considered by the public as a *technical school* of the highest order? Within a few days I have examined with some care the Johns Hopkins Hospital in Baltimore, in regard to the advantages offered for the instruction of medical pupils Here the usual process is reversed. The hospital predominates, but there are laboratories in considerable number with facilities for the teaching of the *science* of medicine, while the *art* is in daily practice in its many splendid wards The medical college proper is yet to be, but the thought tends directly in the line of small classes, personally trained by competent teachers These to be competent require special instruction in the art of teaching, now more lacking in medicine than in any of the great departments of science"

Philadelphia Notes

JAMES E GARRETSON M D, Professor of Anatomy and Dean of the Philadelphia Dental College and Emeritus Professor of Oral Surgery in the Medico Chirurgical College of Philadelphia, died of inflammation of the bowels at Lansdowne, October 26 He was born at Wilmington, Delaware, October' 1828 He studied and practiced dentistry for several years with Dr Thatcher of that city, subsequently he attended lectures in Philadelphia and graduated in dentistry in 1857, and two years later he was graduated in medicine at the University of Pennsylvania He joined Dr D Hayes Agnew in conducting the famous Philadelphia School of Anatomy in 1862, and later was made professor of anatomy and oral surgery in the Philadelphia Dental College He rendered valuable aid in re organizing the Medico Chirurgical College and in placing it upon a broad and secure foundation, and for some twelve years was professor of oral surgery in that institution, being made Emeritus on his retirement from the Medical College a year ago He continued his active connection with the Philadelphia Dental College until his death He was the author of a text-book on oral surgery and also of works of a popular philosophical and literary character, first published under the name of John Darby The principal of these are "Odd Hours of a Physician," "Brushland," "Man and His World," and "Nineteenth Century Sense," which gained for him considerable literary reputation He delighted in the society of students, who held him in such admiration that a Garretsonian Society was formed several years ago, which has met monthly ever since, for discussion of scientific and philosophical questions

Hospital Notes

THE Naval Hospital of New York harbor, located in the Brooklyn Navy Yard, is now undergoing some very important improvements The old structure dates back to 1839, and has long been in need of modernizing treatment Congress has appropriated the sum of $60,000 for its improvement The changes will consist mainly in improving the interior of the old building reconstructing most of the wards and the construction of two new buildings The principal of these will be of brick, three stories high It will contain the mess-hall of the convalescents and a private dining room for the officers, a dispensary, and on the third floor a completely equipped operating room This will have tiled floors, enameled iron furniture and fittings, operating tables of enameled iron and glass, and glass sinks and lavatories In connection with the operating room there will be a "recovery" room, a sterilizing room and a surgeon's chamber and lavatory

Society Notes

THE ALLEGHENY MEDICAL SOCIETY held a meeting in Pittsburg October 15 The following resolutions were adopted

WHEREAS The sanitary conditions of Allegheny County are objectionable in many respects, and

WHEREAS, It is believed that methods for their improvement are readily available, therefore, be it

Resolved, That it is the opinion of this society that every reasonable effort should be made to improve the character of our drinking water by removing from it pernicious material which it contains, and by persistent and energetic measures to prevent its pollution

Resolved, That persons affected with contagious and infectious diseases, including pulmonary consumption, should be subjected to such regulations and restrictions as will afford reasonable protection to the community at large

Resolved, That all establishments for the propagation of vaccine virus should be subject to the most rigid inspection, and such rules for their management adopted as will best prevail against infection It is hereby recommended that the vaccine virus distributed by our boards of health shall be subject to such tests as may be practicable against the presence in it of septic material

THE annual meeting of the Military Tract Society was held in Monmouth, Ill, October 18 The following officers were elected for the ensuing year President, Louis Becker, Knoxville, First Vice-President, C R Harrel, Colchester, Second Vice President E J Mitchell, Roseville Secretary and Treasurer, O B Will Peoria The next meeting of this society will be held in Peoria——The regular meeting of the Kansas City Mo, Academy of Medicine was held October 26——The Jasper County Medical Society held a regular meeting at Newton, Iowa, October 30

St Louis Notes.

The St Louis Medical Society —The program for the meeting of October 31 was made up of papers devoted to diphtheria Dr Meisenbach discussed diphtheria from a surgical standpoint, and while favoring antitoxin, pointed out the fact that as a practical necessity in many cases, intubation and tracheotomy would still be required Dr King treated the subject from a medical point of view, and Drs Martin, W W Graves and Sutter gave their experience in the treatment of the disease with the antitoxic serum The general discussion was most favorable in the light it threw upon the value of the antitoxin, and the majority expressed views in favor of its employment

The St Louis Board of Health now requires that a report of the results of treatment of cases of diphtheria for which it had furnished tubes or serum be made, in order that statistics may be compiled

Detroit Notes

The Wayne County Medical Society —Looking back upon a year of success, the society enters upon a new year with the following officers President, E B Smith (re-elected), Vice-President, W R Henderson, Secretary, T S Hough, Treasurer, C Henri Leonard, Trustees, Drs W J Brand K Gunsolus, L E Maire, T J Parker, O P Eaton The President entertained the society at his home on the evening of the 8th ult About two hundred were present

The Detroit Medical and Library Association —This organization held its annual meeting on Monday, the 8th ult, when the following officers were elected President, E T Tappey, Vice President, C W Hitchcock, Treasurer, A P Biddle, Secretary, W S Anderson The retiring President, Dr Eugene Smith, entertained the members with a sumptuous repast

Detroit Gynecological Society —On October 3 this society held its annual meeting, at which the officers for the ensuing year were elected President, N W Webber, Vice-President, Florence Huson, Secretary-Treasurer, R A Newman A banquet followed the business meeting, given by the retiring President, Dr E T Tappey

Detroit Academy of Medicine —The following officers for the coming year were elected at the annual meeting of this body held on Tuesday, October 9 The President, Dr A H Bigg, entertained the members and invited guests at dinner President, W R. Chittick, Vice-President, D La Ferté, Secretary, C W Hitchcock Director for a term of three years, J E Emmerson

Personal —Dr W J Brand is a candidate for alderman on the Independent ticket He has running against him both a Democrat and a Republican ,

Mortality Report for the Week —The report of the Health Office shows that during the week there were 107 deaths in the city, 52 being children under 5 years of age, 11 occurred from diphtheria

Birth Report for the Week —One hundred and five births were reported for the week, of which 52 were males

Report of Contagious Diseases —There are at present 41 cases of diphtheria, of which 28 are new, 9 cases of scarlet fever, 3 being new, 1 case of smallpox

Louisville Notes

Edward R. Palmer Memorial Meeting, held in the Alderman's Chamber, City Hall, Louisville, Ky, Oct 26, 1895, under the auspices of the Louisville Surgical Society The meeting was called to order by Dr Geo W Griffiths The Secretary, Dr Henry E Tuley, read letters of sympathy, and regrets for inability to attend the meeting from Drs James Nevins Hyde, Chicago, Lyman Beecher Todd, Lexington, Ky, Arch Dixon, Henderson, Ky, John Blake White, New York city, William Judkins, Cincinnati, John A Larrabee and Ap Morgan Vance, of Louisville The President then called upon the speakers appointed

Dr Jos M Mathews said When the committee representing the Louisville Surgical Society asked me to be one of the speakers to-night, I gladly consented, because it was an opportunity to pay a slight tribute, at least, to my dead friend And yet when I was confronted with the duty of writing the same, I must confess that my pen near failed me The question was, from what standpoint shall I speak of Palmer? As Ed Palmer, my friend? As Dr. Palmer the successful physician and surgeon, as Professor Palmer, the distinguished lecturer, or as Palmer, the wit, orator, dilettante? If one were standing on a street corner, and were to see a horse dashing down the street driven by a handsome man, of small features, a small but attractive moustache spectacles adjusted to a nicety and hair brushed as if to attend an evening reception, with sparkling eyes, and with dash and enthusiasm, with neglige shirt and coat to fit the man, with a " Hello, old boy!" That is Ed Palmer If one happened in the sickroom and heard a knock at the outer door, which upon being opened admitted a man above the average height, with a countenance beaming with bright smiles, a hand that clasped another with firmness and fidelity, with a voice as musical as a woman's, with a step as vigorous as a girl's, with words of cheer and hope for the patient, with the bringing of flowers in lieu of medicine, and smiles instead of tears, who with his going out, left the sick and afflicted the better that he had come This is Dr Palmer If your footstep should have been near the door of the lecture hall of the old university down on Chestnut Street, on some pleasant afternoon, you would have seen a man run up the flight of stone steps with the agility of a boy, disappear a moment from view, when the voices of many students and the clapping of many hands would betoken that a favorite stood before the class If you were within distance to hear the clear cut sentences, the logical reasonings and deductions, the beautiful similes, the wonderful descriptions, the drawing of word pictures, amid the shout of applause This was Professor Palmer But if you would see the man in his element, go with me where sat at table friends in a banquet hall Amid the strains of music, the perfume of flowers, the clattering of glasses as they bespoke mirth and good fellowship, the laughter of the guests, the presence of women, this is where Palmer was wont to linger As a voice was heard, like the clear ringing of a bell, so well known to all of us, silence at once prevailed, ears were held expectant, eyes were strained in the effort to see, men and women alike stood for vantage ground, and every word that fell was as a gem divine, every sentence as refreshing as the falling dew to flowers Dramatic in delivery, terse in expression, a voice as musical as a rippling brook, in form like an Apollo, his dress a model, his elocution that of a finished orator, the climax like the calm that succeeds the storm Before the applause has ceased the soft low notes of the voice that had entranced in declamation, now soothes to rest in song, and many an eye is dimmed with tears and hearts made glad as the strain of "My Old Kentucky Home" is sung as he alone could sing it This is Palmer the *superb* Palmer possessed many characteristics that stamped him with originality He was a positive character, and yet, unlike other men, did not make enemies by being so He had no secrets, what he said or did was open to the inspection of the world He was an enthusiast about all things He thought the United States the best of all nations, his State the best of all States, his city the best of all cities His horse could outrun any other horse, and his dog could whip any cur in town His friends, he believed, were as true as steel, and his sons—why, other boys wern't in it! This enthusiasm was born of his nature, and he loved those things so well that he was brought in contact with, that nothing could shake his faith His wit scintillated like the diamond and was as sparkling as champagne Jokes told by him suffered nothing by age A medical gathering without Palmer was stale ale without its froth His nature was continually effervescing, and running over with good humor, with a physique that was perfect, and continued good health, it is no wonder that he always expressed himself as feeling like a "2 year-old," and that he was in the race to win Sorrow never had an abiding place in his breast and he had no time for tears He threw melancholy to the winds, and often physic to the dogs His laughter was contagious and his good humor perennial He did not "fling away ambition," but profited by it His industry was wonderful and his success unbounded He wasn't governed by policy, but every one knew where to place him He was either on one side or the other and knew no middle ground Had he been a politician instead of a doctor, he would have gone to Congress or to the Senate Had he turned his attention to music, the opera would have had a brilliant star He believed that life was worth the living and that croakers should be killed He died as he had lived, he sped through life like a meteor, brightening everything in its path, and went out with a flash I would not clothe his bier in black or lay him away with mourning Rather strew flowers upon his grave and let the rose and hyacinth waft their fragrance back to us, emblematic of his life He speaks to us through laughter and good cheer, and we will remember him in sunshine and not in rain Peace to his ashes!

Dr L S McMurtry said It is an old custom of our profession to render deserved honor and respect to the memory of our departed colleagues by public eulogy An eulogium of any man is confessedly a difficult task, but the embarrassment is greatly increased when, as in the present instance it must be brief and the subject is an active, talented, accomplished, versatile individual, who for years occupied a familiar and conspicuous place in public and professional esteem Edward Rush Palmer was no ordinary man, indeed, in more senses than one, he was a remarkable man, an acute thinker, a facile writer, an erudite and accomplished teacher, an orator, a resourceful and successful practitioner, pursuing his work with the activity of an enthusiastic mind in a vigorous body In all these relations he was prominent among his contemporaries, recognized and esteemed by the profession at home and abroad Though dying in mid career, Palmer had occupied a prominent position in the profession for almost thirty years Few men ushered into responsible professional duties at so early an age are equal to the demands and exigencies imposed upon them He was on the rostrum when he had barely passed his majority, he was actively engaged in practice while almost a youth Others, more competent than I, will speak of his abilities as a teacher I knew him best as a practitioner and a fellow-member of our medical societies For years I have been in cordial and pleasant association with him in these organizations Of late years the medical societies have grown in importance as a means of scientific improvement They are the post-graduate schools of the profession In our city the medical societies have cultivated social along with scientific advantages, bringing the members in more intimate and cordial relations In State and national organizations Palmer was a prominent figure, always a favorite with the delegation from his city and State Upon our local societies he was a regular attendant and participated actively in the discussions He was the life and charm of those occasions when social pleasure abounded Who that knew him can ever forget his great animation, his vivacity, his rich sonorous voice, his personal charm, his bright face and handsome form his magnetism, and the ease and grace of his manner? It was the possession of these qualities, superadded to a thorough knowledge of his profession, which made him such an attractive and impressive figure in the medical societies to which he belonged I would not convey for a moment the impression that his function in these organizations was unimportant, on the contrary, he was a worker Some here present will doubtless recall his last paper read before the Academy last spring, containing many original views upon a subject of great practical importance His papers always bore evidence of careful study, presenting bold and often original views, with practical application As an after-dinner speaker he was the equal of the best the profession of Kentucky has ever had, and this is saying a great deal It will be many years before those who heard his brilliant speech at the banquet in Frankfort three years ago will forget it It was on the occasion of the annual meeting of the Kentucky State Medical Society and while the subject was announced (at his request) as "Where are we at?" the sentiment could more appropriately be expressed as "Kentucky, its products and its people" His remarks were preceded by singing the first lines of that song of which he never tired, 'The Old Kentucky Home" Indeed, he was at his best on such occasions, and carried his audience with him by the magnetism of his person and manner the charm of his voice, and the power of his eloquence He will be keenly missed in our medical societies, where he was an attractive and marked personality The Louisville Surgical Society was, as has already been stated, his special pride and care, he having been the moving spirit in its organization and an active promoter of its usefulness I doubt if those who had only a cursory acquaintance with Palmer during his latest years have any adequate idea of the extent of his general literary culture In an address delivered some years ago he said "I remember when I entered the profession that I despaired of ever being a successful doctor, and became almost half convinced that I had mistaken my vocation Under that cloud I laid my Watson and Stillé aside and spent much of my time with the best poets, essayists, and fiction writers of the age As I remember now the course I took, it is with a pleasure which more than repays me for the serious misgivings I then felt, in thus supplementing the course which my seniors had advised Perhaps it was this experience which has led me to believe in a doctor's being a man of varied learning, and in his cultivating a taste for some improving pursuit or study with which to occupy his leisure hours"

For those who saw Palmer only in his hours of merriment it was difficult to realize that there was a serious and earnest side to his nature His physical endurance was most remarkable, and enabled him to appear as a man of ease and pleasure after a day given to the toil and exactions of a busy doctor's life In him, Nature had blended, in an exceptional manner, apparently opposing qualities When he had passed the fiftieth milestone his body, mind, and heart seemed as gay and undaunted as when in the twenties One could scarcely realize at times that he was a hard working physician and surgeon, devoting his life to our profession and making a handsome competency for his family

For a number of years Palmer was actively engaged in a large general practice During the last decade of his life he limited his practice to the specialty with which he became so prominently identified He was thoroughly in sympathy with all classes of people, and was eminently successful both in general and special practice It needs no argument in this presence to prove that such success is born of merit, that such attainment in our profession comes only by virtue of earnest labor, ability, self-denial and determination

No human character is, or can be, entirely perfect All men have their defects, their sins of omission and commission, and their faults Palmer had his, but of one base quality known to human character he was singularly free, that is hypocrisy Concerning his own life and conduct he had no secrets, and ignored all concealments on all occasions He was equally popular with the people and the profession His humanity drew to him friends from the lowest classes, and his sunny genial nature attracted the highest Nothing could more strikingly attest this than the large representation of all classes of the people who composed the immense gathering on that midsummer day when the last sad rites were held above his lifeless body

Mr President the setting sun, as it sinks into apparent oblivion, illuminates with indescribable splendor the horizon, making beautiful the very mists and clouds which obscure its passing radiance Our friend and colleague passed from life and joy and health and vigor into the silence and apparent oblivion of death almost within an hour Like the setting sun, the memory of his life of cheerful duty, his bright genial nature, his generous friendship and his humanity will illumine the horizon of the present long after his departure When in the years to come, we think of him, we would believe with the poet

> There is no death the stars go down
> To rise upon some fairer shore

Dr T L McDermott, said I scarcely know where to begin the recital of a story, so prolix in detail so embellished in its outline, so redolent of glamour and variety The lovely lines that permeate its majestic horoscope are aglow with all the radiant hues that fancy, in her wildest weavings, could adorn a human mold A career begun in youth with all its exuberant ardor undimmed through a stately manhood and rounded out in its fullest fruition before age had painted a line on its progress or dimmed a single lustre of its renown Possessed of a spontaneity so homogeneous and irresistible that thought and action were simultaneous, he charmed every circle that he entered and left a regretful void as he sped his checkered way There was no half-hearted, lackadaisical symposium in its meteoric flight over breakers or buffets, or velvets or violets it pursued the same tremendous tenor—undaunted by obstacles that seemed insurmountable and hopeful under reverses before which many have succumbed The indomitable pluck that dominated his youth continued perennial to his end A child of audacious genius he was fruitful in resources and skilled by in-

THE OPHIDIANS

BY JOSEPH JONES M D, LL D
MEDICAL DEPARTMENT TULANE UNIVERSITY NEW ORLEANS, LA

In the summer of 1851, I began on Colonel's Island, Liberty County, Ga, a series of investigations upon he anatomic and physiologic differences and relaions of various animals, and especially of closely reated species These have been continued from time o time in my leisure moments, but the interruptions necessary upon the performance of the practical duties of an arduous and exacting profession, and wholly unavoidable during four years of active serve in the Confederate Army, 1861–1865, have prevented the rapid and continuous prosecution, and the desired perfection of these, to me, interesting labors The preparations which I have dissected, injected and preserved, numbering over two thousand, are at present deposited in the Museum of the Medical Department of the University of Louisiana (now Tulane), and serve as illustrations of some of the results of these investigations

The following measurements and drawings with the accompanying *observations are mere fragments* of my labors, which were designed to illustrate the principles of classifications, and the natural relations of animals and especially the relations of species, we hope, however, that they will be sufficient to illustrate the proposition that closely related species present anatomic differences which can not be referred to the action of mere physical forces or to any process of gradual evolution or transmutation of species

We shall confine our observations almost entirely to the *Ophidia* or serpents, as they form a natural order, presenting peculiar anatomic and natural characters, and being without feet, or obvious external organs of locomotion, they appear to present the simplest and best field for the investigation of the anatomic relations of closely allied species

The investigations will be confined chiefly to the relative positions of the internal organs and the minute anatomic differences presented by the position, size and structure of the respiratory organs

As the *Chalcida* form the connecting link between the *Sauria* especially, and the *Ophidia*, we will examine in the first place, the *Ophisauris ventralis Linn*, which is vulgarly regarded as a true *Ophidian*, and familiarly known as the glass snake

GLASS SNAKE (MALE)—OPHISAURIS VENTRALIS—DAUDIN

Anterior extremities rudimentary Inferior extremities rudimentary, ossa innominata present The tongue resembles this organ in the *Scincoidea*, as in the *scorpion*, or red-headed lizard (*Plestodon erythro cephalus* The *Ophisauris* unlike the true *Ophidians* has two lungs Right lung much larger and longer than the left, as shown in the figures The lungs are much more vascular than those of serpents, are without terminal membranous sacs, as in serpents, and are provided with distinct divisions, as in the *Chelonians* and *Sauria* The heart is situated opposite the bifurcation of the bronchial tubes and their junction with the lungs The vascular portion of the lungs lie chiefly below the position of the heart The lungs are not placed symmetrically in the general abdominal and thoracic cavity, but are apparently adapted to the general form of this cavity The left small lung lies *higher up than the right or long lung* Numerous dissections of both male and female specimens of various sizes and ages confirmed the preceding observations

The gall bladder is situated in the liver, and not at a distance from the liver, as in the case of true serpents The general shape and appearance of the liver and also the situation of the gall bladder resembles *more nearly that of the congo snake (Amphiuma)* Distance of gall bladder from anterior border of liver four inches, length of abdominal cavity seven inches The liver lies principally to the right, and the stomach to the left of the median line Spleen disconnected from the pancreas, and on left of median line Pancreas resembles the appearance of this gland in *Ophidians*

This family, *Chalcida*, is evidently from its anatomic structure, closely related to the family *Scincoidea*

Kidneys, lobulated and elongated, resembling in their symmetrical position and in their slender lobulated shape and yellowish color the kidneys of *Ophidians* The kidneys, on the other hand, in the saurians are short and leaf shaped and lobulated in a different manner

OPHIDIA—BROGNIART—SERPENTES—CUVIER

The name *Ophidia*, was first given by M Alexandre Brogniart to this order which comprehends the animals designated by Linnæus under the collective appellation of amphidia serpents, the order *Ophidia* adopted by M M Cuvier includes three families *Anguis*, *Pseudophus ophisaurus*, *Anguis and Aconitas*, *Amphisbæna* and *Serpentes* or true serpents

CROTALOIDEA—CROTALUS DURISSUS (BANDED RATTLESNAKE)

The specimen furnishing the following observations was a female It had 180 large broad plates in the abdomen, 18 broad plates in anterior surface of tail, and 6 divided plates, making 27 plates upon posterior surface of tail

The bronchial tube or windpipe passes down through the entire length of the vascular portion of the lung, and expands finally into a membranous bladder, without cellular divisions, consisting of a strong transparent membrane, the circumference of which when inflated is equal to that of the animal The upper portion of the lungs are thicker and more vascular than the inferior portion, the vascular gradually

of left kidney one inch, breadth, three-sixteenths of an inch Kidneys small and flat Ovaries contained eggs in various stages of development Length of alimentary canal twenty-three inches

CONCLUSIONS

From the preceding observations, it is evident that

While all *Ophidians* are formed upon a general plan and resemble each other in the general form of the body, and structure and arrangement of the internal organs, at the same time the different genera are distinguished by essential differences of structure

Closely related species present essentially the same structure and arrangement and relative position of the internal organs, and the similarity of external appearance and form and of habits and instincts, is attended by a comparative similarity in the structure and relations of the internal organs

It might well be doubted whether, in certain cases, as in the *Crotalus* and *Heterodon*, some of the species of naturalists might not be mere varieties springing originally from the same common stock or original parents

Marked differences are observed in the position and structure of the lungs in different genera, and, in fact, of all the organs, this is the best plan adopted for minute and differential anatomic investigations That the arrangement of the bronchial tube and hexagonal cells is not characteristic of the poisonous *Ophidians* is shown, on the other hand, by the absence of such arrangement in the *Elaps fulvius* (harlequin snake) which is poisonous, and, in the other, by the presence of a similar arrangement of the bronchial tube in the *Coronella getula* (king snake) At the same time there is a wide difference between the structure of the lung in the latter and in the *Crotaloidea*

We can only attribute these marked differences of internal structure in animals of the same growth, the same colors, and subjected to precisely the same climatic influences, to the original endowments or characters of the originators of the different genera, such characters being impressed by the Creator by his direct creative act We can not conceive of a harmless reptile developing in virtue of "innate powers," or in virtue of innate desires and selection a poisonous gland, any more than we can conceive that by such causes the peculiarities of its lung were gradually altered and evolved

These researches establish the important fact, that peculiarities of genera are dependent upon peculiarities of internal structure Similar well-marked differences may be shown to exist in the different classes of warm-blooded animals, but the demonstration is more clear and more valuable in the lower and more simply constructed *Ophidians*

The influence of physical agents upon the developments and variations of species is confined chiefly to alteration of color, size and vigor, and the cutaneous and osseous system, and not to direct structural alterations of the internal organs This will be illustrated by investigations chiefly into the changes of color in the human race, and more especially of albinism in the negro race

The William F Jenks Memorial Prize of the College of Physicians of Philadelphia, for 1895, has been awarded to Dr Abram Brothers, of New York, for an essay on "Infant-mortality During Labor, and its Prevention"—*Medical News*, Nov 9

A REVIEW OF URETERAL SURGERY

An Address delivered by request before the Toledo Academy of Medicine, June 28 1895

BY R HARVEY REED M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY OHIO MEDICAL UNIVERSITY SURGEON TO THE PROTESTANT HOSPITAL

COLUMBUS OHIO

The revelations of modern surgery are daily demonstrating that the ureter, like the appendix vermiformis, has for ages been the cause of numberles fatalities that have been credited to idiopathic causes

Each one of them covers an exceedingly importan sphere in abdominal surgery, and to the modern observer it seems strange that both of them should have escaped careful observation all these years One although having no known physiologic place in the human economy, plays a very decided pathologic role when affected with disease The other has a distinct physiologic function to perform, which if interfered with, is liable to cause grave disturbance, if no rapid dissolution

In glancing over the mortality records of the last decade, we are not surprised at the large death roll attributed to the so-called idiopathic peritonitis especially when we remember that death from disease of, or injury to the ureter, as well as that of the vermiform appendix was seldom if ever recorded Within the last ten years—thanks to aseptic and antiseptic surgery which have made possible the modern advancement of abdominal surgery—surgeons have discovered that much if not all the so-called idiopathic peritonitis is *secondary*, and much of it has been attributed to diseases of the vermiform appendix Likewise the laparotomist has discovered that the ureter, which for cycles unknown has rested undisturbed, has played an important part in the diseases peculiar to the abdominal cavity It is astonishing when we look over the literature pertaining to the ureter that prior to 1880, when an article was written by Emmet, we are unable to find anything on this important subject Following Emmet, we find an article by Staples, written in 1884, and another by Galland, of Paris, in 1885

From this on, reference to the surgical treatment of the ureter becomes more frequent, until up to the present time there have been written more than eighty different articles, pertaining either directly or indirectly to the surgery of the ureters That the ureter opens up a legitimate field of surgery, is beyond a question That the proper surgical treatment of the ureter may save a nephrectomy or even life is without controversy

These facts have led various operators to make numerous experiments, with a view of not only discovering some reliable method for the surgical treatment of the ureter, but to simplify them and, so far as possible, rob them of much of their danger and establish them as legitimate and reliable surgical procedures To Dr Howard A Kelly, of the Johns Hopkins University of Baltimore, the profession owes much for the modern advancement in ureteral catheterization

It is true, Simon sounded the ureter as early as 1875, Grunfield in 1877, Skene in 1889, Morris and Wells in 1893 Yet none of these distinguished authors have given us so much valuable and practical information in reference to the catheterization of the ureter as Kelly With the aid of the cystoscope, the electric light and the delicate ureteral catheter not

The *Elaps fulvius* is also at times, at least, rapacious, and preys upon other reptiles Thus, I have in my possession, an *Elaps* which has swallowed a black snake (*Coluber constrictor*) nearly equal to it in length The stomach has been pushed nearly to the anus, and the gastric juice has completely dissolved the flesh from the bones of the head and cervical vertebra, while the main portion of the snake, including the body and tail lying beyond the stomach in the distended esophagus, is in a state of perfect preservation The bronchial tube extends down alone for five and one half inches below the apex of the heart, where it expands into a bright vascular sac, with small well-defined cells The rudimentary lung opens just opposite the apex of the heart The cells of the vascular portions of the lungs are perfect hexagonal figures The cells are much smaller than in the lungs of the *Crotalus*, *Crotalophorus* and *Trigonocephalus*, the largest being not more than one fiftieth of an inch in diameter, and the smallest not less than one one-hundredth of an inch

In the *Elaps fulvius*, the bronchial tube does not extend through the vascular portion of the lungs, as in *Crotalus*, *Crotalophorus* and *Trigonocephalus*, but after the expansion of the vascular pulmonary bag, its rudimentary existence is marked by a fibrous band running down the central portion of the vascular lung Length of vascular portion of lung, two and one-fifth inches

It will be observed that marked differences of anatomic structure and especially of the lungs, are found in the four genera of poisonous snakes found in the Southern United States of America, viz, *Crotalus*, *Crotalophorus*, *Trigonocephalus* and *Elaps* The three former correspond to a certain degree in external conformation and internal anatomic structure, the latter differs in both external conformation and internal anatomic structure The *Elaps fulvius* resembles in the general shape of the body, as well as in the shape of the head and neck, the *Rhinostoma coccinea*, of Blumenbach The position of the heart, and the relations of the bronchial tube, as well as the general shape of the organs are similar in the two genera Like the lung of the *Elaps fulvius*, that of the *Rhinostoma* begins below the apex of the heart

Schlegel errs greatly when he associates the *Rhinostoma coccinea* with the *Heterodontes*, for it differs from them, not only in its external form, but also in the structure, relative size and position of the internal organs and especially in the position and structure of the lungs In the American vipers (*Heterodon Niger*, *H platirhinos* and *H simus*) the bronchial tube joins the lungs or vascular portion at an acute angle, and one branch of the lung runs up as a distinct sac, along the bronchial tube toward the head

OPHISAURIS VENTRALIS—DAUDIN—GLASS SNAKE (MALE)

Length of this snake twenty-five inches length of right lung three eighths inches, left lung one-third inch, tail thirteen and five-eighths inches, distance from tip of head to apex of heart three inches, to superior border of liver three-fourths of an inch, length of the liver one inch, breadth four-tenths of an inch

CROTALOIDEA—CROTALUS DURISSUS—(BANDED RATTLESNAKE)

The specimen furnishing the following measurements was a female, length of snake from extremity of head to the junction of the rattles with the tail, fifty-one inches, length of head and body, forty-seven and one-half inches, length of tail, three and one half inches, length of abdominal cavity forty-seven and one half inches, distance of apex of nose to apex of heart, nineteen and one half inches, to superior border of liver, twenty inches, length of liver, twelve inches, breadth, one and three-tenths inches, distance of inferior border of liver from gall bladder, one and one half inches, as usual there was a small separate liver along the course of the vena cava

CROTALOPHORUS MILIARIUS—(GROUND RATTLESNAKE, HOGNOSE RATTLESNAKE)

This specimen was a male and yielded the following measurements length of head and body, sixteen eight-tenths inches, length of tail, two and seven-tenths inches, length of abdominal and thoracic cavity (as there is no diaphragm, the entire cavity is included under the head) sixteen inches, length of alimentary canal, sixteen and one-half inches, distance of apex of heart from extremity of head, six and four tenths inches, length of vascular portion of lungs, four and four-tenths inches, distance from end of head to superior border of liver, six and seven-tenths inches, length of liver, two and eight-tenths inches, breadth of liver, three tenths of an inch

TRIGONOCEPHALUS CONTORTRIX—LINNÆUS—(COPPERHEAD)

The length of this specimen (female) from which these measurements were taken was thirty-one and one half inches, length of head and body twenty-seven and one half inches, length of tail four inches, number of abdominal plates 153, of subcaudal plates, 11, the tail terminated in a horny point, or hook-like button, which appears to be the representation of the rattle in the *Crotalus* Length of abdominal and thoracic cavity twenty-six inches, length of alimentary canal twenty-six inches, distance from end of head or point of nose, or snout, to apex of heart, nine and one half inches, length of vascular portion of lung eight inches, distance of extremity of head from superior portion of liver, nine and three-fourths inches, superior border of liver situated one-fourth of an inch from the apex of heart Length of liver, five inches, breadth three fourths of an inch, length of right kidney three and one-half inches, breadth of right kidney, four sixteenths of an inch, length of left kidney two and one-half inches, breadth, five-sixteenths of an inch, distance of inferior border of kidneys from anus, one and one-half inches

ELAPS FULVIUS—LINNÆUS—(BEAD SNAKE—HARLEQUIN SNAKE)

The specimen furnishing the following measurements was a female length, twenty-six and one-half inches, it had 221 abdominal plates and 34 subcaudal plates Distance of apex of heart to extremity of head, five and one-half inches, distance of superior portion of liver from apex of heart, six and one half inches, distance of apex of heart from superior border of liver one inch, length of liver six inches, breadth, three tenths of an inch,-length of abdominal cavity, twenty-three and three-fourths inches, length of head and body, twenty-three and three-fourth inches, length of tail, two and one-fourth inches, length of right kidney, one and one half inches, breadth, two-tenths of an inch, length

of left kidney one inch, breadth, three-sixteenths of an inch Kidneys small and flat Ovaries contained eggs in various stages of development Length of alimentary canal twenty-three inches

CONCLUSIONS

From the preceding observations, it is evident that

While all *Ophidians* are formed upon a general plan and resemble each other in the general form of the body, and structure and arrangement of the internal organs, at the same time the different genera are distinguished by essential differences of structure

Closely related species present essentially the same structure and arrangement and relative position of the internal organs, and the similarity of external appearance and form and of habits and instincts, is attended by a comparative similarity in the structure and relations of the internal organs

It might well be doubted whether, in certain cases, as in the *Crotalus* and *Heterodon*, some of the species of naturalists might not be mere varieties springing originally from the same common stock or original parents

Marked differences are observed in the position and structure of the lungs in different genera, and, in fact, of all the organs, this is the best plan adopted for minute and differential anatomic investigations That the arrangement of the bronchial tube and hexagonal cells is not characteristic of the poisonous *Ophidians* is shown, on the other hand, by the absence of such arrangement in the *Elaps fulvius* (harlequin snake) which is poisonous, and, in the other, by the presence of a similar arrangement of the bronchial tube in the *Coronella getula* (king snake) At the same time there is a wide difference between the structure of the lung in the latter and in the *Crotaloidea*

We can only attribute these marked differences of internal structure in animals of the same growth, the same colors, and subjected to precisely the same climatic influences, to the original endowments or characters of the originators of the different genera, such characters being impressed by the Creator by his direct creative act We can not conceive of a harmless reptile developing in virtue of "innate powers," or in virtue of innate desires and selection a poisonous gland, any more than we can conceive that by such causes the peculiarities of its lung were gradually altered and evolved

These researches establish the important fact, that peculiarities of genera are dependent upon peculiarities of internal structure Similar well-marked differences may be shown to exist in the different classes of warm-blooded animals, but the demonstration is more clear and more valuable in the lower and more simply constructed *Ophidians*

The influence of physical agents upon the developments and variations of species is confined chiefly to alteration of color, size and vigor, and the cutaneous and osseous system, and not to direct structural alterations of the internal organs This will be illustrated by investigations chiefly into the changes of color in the human race and more especially of albinism in the negro race

A REVIEW OF URETERAL SURGERY

An Address delivered by request before the Toledo Academy of Medicine June 28, 1895

BY R HARVEY REED M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY OHIO MEDICAL UNIVERSITY SURGEON TO THE PROTESTANT HOSPITAL

COLUMBUS OHIO

The revelations of modern surgery are daily demonstrating that the ureter, like the appendix vermiformis, has for ages been the cause of numberless fatalities that have been credited to idiopathic causes

Each one of them covers an exceedingly important sphere in abdominal surgery, and to the modern observer it seems strange that both of them should have escaped careful observation all these years One, although having no known physiologic place in the human economy, plays a very decided pathologic rôle when affected with disease The other has a distinct physiologic function to perform, which if interfered with, is liable to cause grave disturbance, if not rapid dissolution

In glancing over the mortality records of the last decade, we are not surprised at the large death roll attributed to the so-called idiopathic peritonitis, especially when we remember that death from disease of, or injury to the ureter, as well as that of the vermiform appendix was seldom if ever recorded Within the last ten years—thanks to aseptic and antiseptic surgery which have made possible the modern advancement of abdominal surgery—surgeons have discovered that much if not all the so-called idiopathic peritonitis is *secondary*, and much of it has been attributed to diseases of the vermiform appendix Likewise the laparotomist has discovered that the ureter, which for cycles unknown has rested undisturbed, has played an important part in the diseases peculiar to the abdominal cavity It is astonishing when we look over the literature pertaining to the ureter that prior to 1880, when an article was written by Emmet, we are unable to find anything on this important subject Following Emmet, we find an article by Staples, written in 1884, and another by Galland, of Paris, in 1885

From this on, reference to the surgical treatment of the ureter becomes more frequent, until up to the present time there have been written more than eighty different articles, pertaining either directly or indirectly to the surgery of the ureters That the ureter opens up a legitimate field of surgery, is beyond a question That the proper surgical treatment of the ureter may save a nephrectomy or even life is without controversy

These facts have led various operators to make numerous experiments, with a view of not only discovering some reliable method for the surgical treatment of the ureter, but to simplify them and, so far as possible, rob them of much of their danger and establish them as legitimate and reliable surgical procedures To Dr Howard A Kelly, of the Johns Hopkins University of Baltimore, the profession owes much for the modern advancement in ureteral catheterization

It is true, Simon sounded the ureter as early as 1875, Grunfield in 1877, Skene in 1889, Morris and Wells in 1893 Yet none of these distinguished authors have given us so much valuable and practical information in reference to the catheterization of the ureter as Kelly With the aid of the cystoscope, the electric light and the delicate ureteral catheter, not

The *Elaps fulvius* is also at times, at least, rapacious, and preys upon other reptiles Thus, I have in my possession, an *Elaps* which has swallowed a black snake (*Coluber constrictor*) nearly equal to it in length The stomach has been pushed nearly to the anus, and the gastric juice has completely dissolved the flesh from the bones of the head and cervical vertebra, while the main portion of the snake, including the body and tail lying beyond the stomach in the distended esophagus, is in a state of perfect preservation The bronchial tube extends down alone for five and one half inches below the apex of the heart, where it expands into a bright vascular sac, with small well-defined cells The rudimentary lung opens just opposite the apex of the heart The cells of the vascular portions of the lungs are perfect hexagonal figures The cells are much smaller than in the lungs of the *Crotalus*, *Crotalophorus* and *Trigonocephalus*, the largest being not more than one-fiftieth of an inch in diameter, and the smallest not less than one one-hundredth of an inch

In the *Elaps fulvius*, the bronchial tube does not extend through the vascular portion of the lungs, as in *Crotalus*, *Crotalophorus* and *Trigonocephalus*, but after the expansion of the vascular pulmonary bag, its rudimentary existence is marked by a fibrous band running down the central portion of the vascular lung Length of vascular portion of lung, two and one-fifth inches

It will be observed that marked differences of anatomic structure and especially of the lungs, are found in the four genera of poisonous snakes found in the Southern United States of America, viz, *Crotalus*, *Crotalophorus*, *Trigonocephalus* and *Elaps* The three former correspond to a certain degree in external conformation and internal anatomic structure, the latter differs in both external conformation and internal anatomic structure The *Elaps fulvius* resembles, in the general shape of the body, as well as in the shape of the head and neck, the *Rhinostoma coccinea*, of Blumenbach The position of the heart, and the relations of the bronchial tube, as well as the general shape of the organs are similar in the two genera Like the lung of the *Elaps fulvius*, that of the *Rhinostoma* begins below the apex of the heart

Schlegel errs greatly when he associates the *Rhinostoma coccinea* with the *Heterodontes*, for it differs from them, not only in its external form, but also in the structure, relative size and position of the internal organs and especially in the position and structure of the lungs In the American vipers (*Heterodon Niger H platyrhinos* and *H simus*) the bronchial tube joins the lungs or vascular portion at an acute angle, and one branch of the lung runs up as a distinct sac, along the bronchial tube toward the head

OPHISAURIS VENTRALIS—DAUDIN—GLASS SNAKE (MALE)

Length of this snake twenty-five inches length of right lung three eighths inches, left lung one-third inch, tail thirteen and five-eighths inches, distance from tip of head to apex of heart three inches, to superior border of liver three-fourths of an inch, length of the liver one inch, breadth four-tenths of an inch

CROTALOIDEA—CROTALUS DURISSUS—(BANDED RATTLESNAKE)

The specimen furnishing the following measurements was a female, length of snake from extremity of head to the junction of the rattles with the tail, fifty-one inches, length of head and body, forty-seven and one-half inches, length of tail, three and one half inches, length of abdominal cavity forty-seven and one half inches, distance of apex of nose to apex of heart, nineteen and one half inches, to superior border of liver, twenty inches, length of liver, twelve inches, breadth, one and three-tenths inches, distance of inferior border of liver from gall bladder, one and one half inches, as usual there was a small separate liver along the course of the vena cava

CROTALOPHORUS MILIARIUS—(GROUND RATTLESNAKE, HOGNOSE RATTLESNAKE)

This specimen was a male and yielded the following measurements length of head and body, sixteen eight tenths inches, length of tail, two and seven-tenths inches, length of abdominal and thoracic cavity (as there is no diaphragm, the entire cavity is included under the head) sixteen inches, length of alimentary canal, sixteen and one-half inches, distance of apex of heart from extremity of head, six and four-tenths inches, length of vascular portion of lungs, four and four-tenths inches, distance from end of head to superior border of liver, six and seven tenths inches, length of liver, two and eight-tenths inches, breadth of liver, three tenths of an inch

TRIGONOCEPHALUS CONTORTRIX—*LINNÆUS*—(COPPERHEAD)

The length of this specimen (female) from which these measurements were taken was thirty-one and one-half inches, length of head and body twenty-seven and one half inches, length of tail four inches, number of abdominal plates 153, of subcaudal plates, 44 the tail terminated in a horny point, or hook-like button, which appears to be the representation of the rattle in the *Crotalus* Length of abdominal and thoracic cavity twenty-six inches, length of alimentary canal twenty-six inches, distance from end of head or point of nose, or snout, to apex of heart, nine and one half inches, length of vascular portion of lung eight inches, distance of extremity of head from superior portion of liver, nine and three-fourths inches, superior border of liver situated one-fourth of an inch from the apex of heart Length of liver, five inches, breadth, three fourths of an inch, length of right kidney three and one-half inches, breadth of right kidney, four-sixteenths of an inch, length of left kidney two and one-half inches, breadth, five sixteenths of an inch, distance of inferior border of kidneys from anus, one and one-half inches

ELAPS FULVIUS—LINNÆUS—(BEAD SNAKE—HARLEQUIN SNAKE)

The specimen furnishing the following measurements was a female length, twenty-six and one-half inches, it had 221 abdominal plates and 34 subcaudal plates Distance of apex of heart to extremity of head, five and one-half inches, distance of superior portion of liver from apex of heart, six and one half inches, distance of apex of heart from superior border of liver one inch, length of liver six inches, breadth, three-tenths of an inch, length of abdominal cavity, twenty-three and three-fourths inches, length of head and body, twenty-three and three-fourth inches, length of tail, two and one-fourth inches, length of right kidney, one and one-half inches, breadth, two-tenths of an inch, length

of left kidney one inch, breadth, three-sixteenths of an inch Kidneys small and flat Ovaries contained eggs in various stages of development Length of alimentary canal twenty-three inches

CONCLUSIONS

From the preceding observations, it is evident that

While all *Ophidians* are formed upon a general plan and resemble each other in the general form of the body, and structure and arrangement of the internal organs, at the same time the different genera are distinguished by essential differences of structure

Closely related species present essentially the same structure and arrangement and relative position of the internal organs, and the similarity of external appearance and form and of habits and instincts, is attended by a comparative similarity in the structure and relations of the internal organs

It might well be doubted whether, in certain cases, as in the *Crotalus* and *Heterodon*, some of the species of naturalists might not be mere varieties springing originally from the same common stock or original parents

Marked differences are observed in the position and structure of the lungs in different genera, and, in fact, of all the organs, this is the best plan adopted for minute and differential anatomic investigations That the arrangement of the bronchial tube and hexagonal cells is not characteristic of the poisonous *Ophidians* is shown, on the other hand, by the absence of such arrangement in the *Elaps fulvius* (harlequin snake) which is poisonous, and, in the other, by the presence of a similar arrangement of the bronchial tube in the *Coronella getula* (king snake) At the same time there is a wide difference between the structure of the lung in the latter and in the *Crotaloidea*

We can only attribute these marked differences of internal structure in animals of the same growth, the same colors, and subjected to precisely the same climatic influences, to the original endowments or characters of the originators of the different genera, such characters being impressed by the Creator by his direct creative act We can not conceive of a harmless reptile developing in virtue of "innate powers," or in virtue of innate desires and selection a poisonous gland, any more than we can conceive that by such causes the peculiarities of its lung were gradually altered and evolved

These researches establish the important fact, that peculiarities of genera are dependent upon peculiarities of internal structure Similar well-marked differences may be shown to exist in the different classes of warm-blooded animals, but the demonstration is more clear and more valuable in the lower and more simply constructed *Ophidians*

A REVIEW OF URETERAL SURGERY

An Address delivered by request before the Toledo Academy of Medicine June 28 1895

BY R HARVEY REED M D

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY OHIO MEDICAL UNIVERSITY SURGEON TO THE PROTESTANT HOSPITAL
COLUMBUS OHIO

The revelations of modern surgery are daily demonstrating that the ureter, like the appendix vermiformis, has for ages been the cause of numberless fatalities that have been credited to idiopathic causes

Each one of them covers an exceedingly important sphere in abdominal surgery, and to the modern observer it seems strange that both of them should have escaped careful observation all these years One, although having no known physiologic place in the human economy, plays a very decided pathologic rôle when affected with disease The other has a distinct physiologic function to perform, which if interfered with, is liable to cause grave disturbance, if not rapid dissolution

In glancing over the mortality records of the last decade, we are not surprised at the large death roll attributed to the so-called idiopathic peritonitis, especially when we remember that death from disease of, or injury to the ureter, as well as that of the vermiform appendix was seldom if ever recorded Within the last ten years—thanks to aseptic and antiseptic surgery which have made possible the modern advancement of abdominal surgery—surgeons have discovered that much if not all the so-called idiopathic peritonitis is *secondary*, and much of it has been attributed to diseases of the vermiform appendix Likewise the laparotomist has discovered that the ureter, which for cycles unknown has rested undisturbed, has played an important part in the diseases peculiar to the abdominal cavity It is astonishing when we look over the literature pertaining to the ureter that prior to 1880, when an article was written by Emmet, we are unable to find anything on this important subject Following Emmet, we find an article by Staples, written in 1884, and another by Galland, of Paris, in 1885

From this on, reference to the surgical treatment of the ureter becomes more frequent, until up to the present time there have been written more than eighty different articles, pertaining either directly or indirectly to the surgery of the ureters That the ureter opens up a legitimate field of surgery, is beyond a question That the proper surgical treatment of the ureter may save a nephrectomy or even life is without controversy

These facts have led various operators to make numerous experiments, with a view of not only discovering some reliable method for the surgical treatment of the ureter, but to simplify them and, so far as possible, rob them of much of their danger and establish them as legitimate and reliable surgical procedures To Dr Howard A Kelly, of the Johns Hopkins University of Baltimore, the profession owes much for the modern advancement in ureteral catheterization

It is true, Simon sounded the ureter as early as 1875, Grunfield in 1877, Skene in 1889, Morris and Wells in 1893 Yet none of these distinguished authors have given us so much valuable and practical information in reference to the catheterization of the ureter as Kelly With the aid of the cystoscope, the electric light and the delicate ureteral catheter not only the walls of the bladder may be subjected to ocular inspection, but either ureters may be sounded or catheterized at the will of the operator The ureters may be catheterized without the cystoscope by simply depending on the touch, but this is not nearly so reliable, and where the walls of the bladder are thickened by disease it is often impossible With the aid of the ureteral catheter, such as I herewith exhibit, devised by Dr Kelly, we are enabled to relieve stenosis of the ureter where it occurs within the lower third or where there is disease of one or both kidneys, we are enabled by catheterizing each ureter to determine by an analysis of the urine collected in this manner whether both of the kidneys are diseased, or if but one which one The use of the ureteral catheter is therefore, not only an important factor in the diagnosis of renal diseases, but of no small value for the treatment of stenosis of the ureter

Where valve formation and stricture of the ureter occurs so high up as to be beyond the reach of the catheter or sound, resulting in hydro or pyonephrosis nephrotomy and even nephrotomy may often be avoided by an operation with a view to the re-establishment of the lumen of the ureter

Fenger of Chicago reports a number of cases of this character relieved by plastic operation after the method of Heineke-Mikulicz, which consists in a *longitudinal* division of the stricture and transverse union of the longitudinal wound which shortens the ureter in proportion to the length of the stricture Professor Fenger prefers this method of operating to that of resection of the stricture as performed by Kuster Yet they both require great care in order to avoid extravasation of urine and they are both done at the expense of the length of the ureter Either method, however, we consider much more desirable than implanting the ureter into the vagina, perineum or the abdominal walls

Page of London, reports several cases of rupture of the ureter in the *Annals of Surgery*, for May, 1894, the treatment of which was anything but satisfactory He closed his article by saying 'that the question of *treatment can not be closed without a consideration* of the possibility of suture of the ureter and the prevention thereby of all the trouble which these various cases suffered Notwithstanding this suggestion, he rather discourages the plastic operation and suggests in the treatment of a ruptured or stenosed ureter that, 'it is one thing to find and expose the ureter in these conditions, and quite another thing when there is no fixed calculus to mark its position '

Herman Mynter, of Buffalo, New York, reports a case, in the *Annals of Surgery*, December, 1893, of valvular stricture of the ureter, which was closed by a plastic operation, which resulted successfully and in fifteen days after the operation the patient was discharged feeling well In a recent number of the *University Medical Magazine*, Prof Chas B Penrose, of Philadelphia, reports a successful operation where the ureter was involved by a scirrhous cancer of the cervix uterus, in which it became necessary to excise an inch of the ureter, which was afterward implanted high up in the bladder, after Van Hook's method In this case there was no symptom of bladder or renal disturbance and the patient left the hospital twenty days after the operation to all appearance well, although six months later she is reported suffering pain in the right iliac region, suggesting the probability of recurrence of the disease This operation shows that the implantation of the ureter high up in the bladder is a *successful* and practical procedure

In an exhaustive paper read by Dr Weller Van Hook of Chicago, before the Section of Surgery and Anatomy of the AMERICAN MEDICAL ASSOCIATION at its Milwaukee meeting, the Doctor arrived at some thirty-two conclusions in reference to the surgical treatment of the ureter among which he states, in conclusion 6 "Longitudinal wounds of the ureter at any point, heal without difficulty in the absence of septic processes, under the influence of ample drainage "

In conclusion 14, he says "In complete transverse injuries of the ureter in continuity, union must not be attempted by suture "

In conclusion 16, he advises "In complete transverse injuries of the ureter very near the bladder, the duct may be implanted, but with less advantage, into the bladder directly " The feasibility of this latter method is demonstrated in the case referred to above, by Professor Penrose In conclusion 15, Dr Van Hook states that "In complete transverse injuries of the ureter in continuity, union without subsequent scar contraction may be obtained by the writer's method of lateral implantation "

Where the ureter is too short to reach the bladder, Dr Van Hook recommends the making of a vesical diverticulum This is accomplished

1 By implanting the ureter upon the skin of the abdomen in the median line as near the bladder as possible Close the abdominal walls as usual, except for the presence of the ureter

2 When the patient is fully recovered from the primary operation, open the structures composing the abdominal wall, between the ureter and the pubes, down to the peritoneum and bladder The peritoneum must not be opened The bladder may be extended and raised exactly as in suprapubic cystotomy

3 Make two incisions in the bladder parallel to the median line, beginning as near as possible to the peritoneum without prejudice to its integrity, carry them down at a distance of about 15 mm apart *toward the neck* of the bladder under the guidance of the finger With scissors curved on the flat, the two incisions are now united at the lowest point and hemorrhage is controlled with pressure forceps It will be seen that we now have at our disposal a vesical flap of considerable extent hinged above by a nutrient pedicle

4 The ureter is loosened from the skin and brought well down toward the flap, which is simultaneously raised to meet it The vesical flap is firmly fastened back in its new position by catgut sutures, passing through the neighboring muscles of the fascia, and the end of the ureter is held in position by light catgut sutures which pass through the loose peri-ureteral connective tissue, if possible, and through the muscular structures near at hand

5 We are now in position to sew together the edges of the flap to form a tube, in the upper end of which the ureter is introduced, and to carry a similar row of light catgut sutures down the bladder wound itself. The lower angle of the vesical opening would best be left open for the sake of drainage It will in all probability cause no trouble in healing The upper part of the skin wound together with the fasciæ may be closed Under careful antiseptic treatment this procedure ought to be practicable, and as easy as the majority of the operations daily undertaken

The Doctor says he has practiced this method with considerable success on the cadaver, and argues that "we may safely say that, without opening the peritoneum, the bladder can be plastically extended to meet the ureter when that duct is brought out of the abdomen at any point not exceeding three and one-fourth inches inferior to the umbilicus" Hypothetically this is a very handsome operation, but before we would feel like indorsing it we would like to see its results on the *living* rather than the *moribund* subject There is no question but what the ureter, when sufficiently long, could be implanted in the bladder, or it may be successfully connected with the vagina, but we are frank to admit that we do not consider the latter a very advisable operation, for reasons which we shall state hereafter The question now arises, What method of surgical procedure shall we adopt where it is impossible to perform a plastic operation on the ureter that will unite it, when severed, or that will connect it with some other than normal connection with the bladder In order to furnish, if possible, a connecting link in this very important part of the surgical treatment of the ureter, we have conducted numerous experiments with a view of implanting the ureter into the rectum, and so far as the implantation of a single ureter is concerned, our experiments have been fairly satisfactory and successful, as you will see by the specimen herewith submitted for examination

Dr Van Hook, however, takes serious exceptions to this method of disposing of the ureter In his criticism he says "The implantation of one or both ureters into the rectum is absolutely unjustifiable under all circumstances," and gives as his principal reason that these delicate tubes are inserted into the filthy rectum or intestine filled with solid, liquid or gaseous material to distend and defile the ureter and the pelvis of the kidney Almost with the same breath the Doctor advises the implantation of the ureters into some portion of the abdominal wall and bring it out on the surface of the skin Just as if the skin were not septic and would subject the ureter to septic infection as well as the intestine, beside placing the ureter in an unfavorable position while the patient is on his back for natural drainage, to say nothing of being occluded by the bowel when the patient is in the erect position

Did it ever occur to the Doctor that the ductus communis choledochus in connection with the pancreatic duct commit the awful crime of discharging their contents into the descending portion of the duodenum? It would appear from the criticisms of Dr Van Hook that even this would be unjustifiable under all circumstances The Doctor seems to have forgotten that there is a law of natural immunity which not only protects us from infection from the septic material of the duodenum which might otherwise cause sickness and death, but protects the other natural channels from the same dangers, and makes it possible for him to make an opening for the ureters through the integument and the patient live, who if it were not for this law of natural immunity would become infected and die

We were not neglectful of the fact that the intestines were septic, but we maintain that it gives the patient a better chance for recovery, especially where only one ureter needs to be implanted It is certainly a much more desirable operation than bringing the ureter out to the surface of the skin and afflicting the patient with a urinary fistula the remainder of his days The chance for stenosis is much greater on the one hand than on the other In fact, there is more liability of stenosis where the ureter is brought out through the intestines and the walls of the abdomen than where it is implanted in the bowel or rectum Where implantation into the rectum is successful, the patient is not disturbed with the foul odors of decomposing urine as he is in the case where it is implanted in the walls of the abdomen or the vagina If I were to make a choice to day between implanting the ureter in the walls of the abdomen or vagina and making a nephrectomy, I should prefer the latter, with the single exception of where there were but one kidney left to operate on, and then it would be folly to perform a nephrectomy and there would be nothing left but to implant the ureter in the walls of the abdomen, vagina, or the intestinal tract To the unbiased mind it seems to me there is no question as to which of these three methods would be preferable It is true in either one if septic infection or stenosis takes place, a nephrectomy can be made afterward but if this is not necessary, where each are successful, there is no question as to the comfort of the patient on one hand and the discomfort on the other

In the case operated on by Dr Leet of Scranton, Pa , where the ureter was implanted into the rectum and the patient recovered from the operation, but died subsequently of an entirely different disease not connected with the operation, I am told the patient suffered no inconvenience from the ureter being implanted into the rectum, and when a post mortem was made there was found to be complete union without consequent nephritis so frequently referred to by Dr Van Hook as the result of septic infection, neither was there stenosis of the ureter itself which he prognosticates as a most probable sequela in these operations

Practical experience is always preferable to hypothetical theory Notwithstanding the severe criticisms offered by Dr Van Hook, on the implantation of the ureters into the rectum, we find in an article by Chaput, published in the *Archives Generales de Medicine*, January, 1894, that this distinguished operator performed this operation upon a patient Sept 13, 1892, in which he states the results of the operation were excellent Fever was entirely absent and the patient recovered without a single complication In speaking of this operation, Deforest, in an editorial published in the *Annals of Surgery* for August, 1894, page 198, says "At the end of a year a comparison of the discharge from the rectum and from the bladder for twenty-four hours gave the following results vesical urine, 1,250 cubic centimeters, urea 24 grams per liter Liquid material eliminated by the rectum, 270 cubic centimeters, urea, 4 5 grams per liter The patient has three liquid movements daily which contain solid matter in suspension These passages are easily retained in the rectum, and there is no discomfort experienced The left kidney is not enlarged and the amount of urine excreted is not abundant The diminution in the amount of urea in the urine of this side is explained by the fact that secondary changes had occurred in the kidney as a result of the contraction of the orifice of the ureter during the existence of the fistula"

On Nov 25, 1892, Chaput again implanted the ureter into the rectum for chronic inflammatory thickening of the bladder Three months after the operation the general condition of the patient was fairly good There were but four or five passages daily The anastomosis of the right ureter with the cæcum was decided upon, and this operation was performed on the first of March, 1893, or about three months after the implantation of the left ureter In this case the ureter was as large as the thumb and its walls were thickened and congested No fever followed the operation, but the patient became comatose and died on the same day, which confirmed the conclusion arrived at by the writer in his experimental work, that the implantation of one ureter was comparatively free from danger but the implantation of both was a hazardous operation Chaput "concludes as a result of this observation that this form of anastomosis is a favorable one, since, notwithstanding the adverse conditions, the operation itself was successful and was free from unfavorable complications either on the side of the kidney or on the side of the intestine The frequency of the discharges from the rectum, which decreased toward the last, is to be attributed to the polyuria existing in a kidney already diseased It is fair to assume that eventually the large intestine would have become sufficiently dilated to act as a reservoir for the urine, and so render the evacuations less frequent"

After briefly reviewing the progress made in the last few years in the surgery of the ureter, we are led without further light, to the following legitimate conclusions

1 That where it is possible, a traumatism of the ureter should be repaired by a plastic operation which has for its object the union of the distal and proximal ends of the ureter

2 Where it is possible to reach the superior portion of the bladder it is advisable to implant the distal end of the ureter into the bladder

3 Where it is impossible to either unite the distal or proximal end or implant the distal end into the bladder, we would advise, as a matter of choice the implantation of the ureter into the alimentary canal, rather than into the vagina or the making of a fistulous opening through the skin

SOME POINTS IN THE SURGERY OF THE URETERS

BY WELLER VAN HOOK, A B, M D

CHICAGO

An interesting work on ureteral surgery[1] has recently been published in Paris The author devotes his entire attention to anatomy, to the methods of exposing the ureter for surgical treatment, to ureterotomy for removal of calculi and for the relief of stenosis, and to resection Inasmuch as he omits the consideration of such important branches of the subject as diagnosis the use of catheterization of the ureters for various purposes and the implantation of the ureters upon the skin, into the intestinal tract and into the bladder, his work must be regarded as a valuable and timely discussion of the topic touched upon, but not as the systematic treatise upon the general subject of surgical ureteral diseases which the title and the size of the volume lead one to expect

The position assumed by the present writer upon a former occasion in reference to the subjects of suturing longitudinal wounds of the ureter and of union of that duct after transverse division, have been adversely criticised, although Dr Glantenay agrees in the main with his conclusions upon other topics

In that article it was shown that unsutured longitudinal wounds of the ureter must heal by granulation, inasmuch as the continual passage of the urine out of the wound would suffice to prevent the accurate coaptation of the edges of the duct necessary to *prima intentio* Provision for the free escape of urine by drainage being presupposed, the abundant connective tissue in the neighborhood of the tube must soon be covered by granulations, to which the duct will speedily become attached The wound edges will then be in position to favor their epidermization, and as no more than normal resistance will be offered to the outflow of urine by the bladder, the discharge of the fluid will soon take place by the natural passages instead of through the drainage tract after the drainage tube is removed Since the mucous membrane strongly tends, during the time the wound is open, to proliferate over the granulations extending from their edges toward the drainage tract, the lumen of the tube after healing has occurred will be, if altered at all, greater at the site of injury, just as the urethra, after external urethrotomy for stricture, has a greater caliber at the site of the longitudinal incision The advantage of surgically utilizing this mode of repair lies in the fact that if scar contraction take place after such healing it must bring about a shortening of the tube rather than a diminution of its caliber

Dr Glantenay holds that we should, as far as possible adopt the suture in dealing with these wounds. There are several manifest objections, however, to the application of sutures to longitudinal wounds The first of these is that the tube is so small and delicate and its situation often so difficult of access that the operation will usually be trying and unsatisfactory. The record of Tuffier's experiments is sufficient proof of this fact if demonstration be required

A second objection is that the needle is liable to penetrate the mucosa of the tube in the course of the application of a number of sutures, and to leave fastened in its lumen a thread upon which calculous deposits may form Should suppuration occur from previous infection of the urine, or from contamination at the time of operation the presence of sutures would be worse than useless, since they would act as foreign bodies, keeping up a purulent discharge, and would also act as centers for the deposit of urinary salts

Beside these objections the sutures must inevitably produce an immediate coarctation of the tube, seeing that they can only close the wound by making tangential traction upon its walls

Dr Glantenay has collected fifteen cases of longitudinal incisions in the ureter, of which five were sutured with silk, the remainder being allowed to heal without stitches Of the five patients in whose cases sutures were placed one died Of the remainder, one had a persistent fistula One patient died, among the ten treated without suture Of the nine which recovered under this treatment, three had temporary fistulæ, a fact scarcely worth mentioning, since the very statement that sutures were not applied would lead us to expect a temporary discharge of urine by the drainage tract One case is also recorded in the table with the remark "guerison, fistule?" Obviously, the number of cases thus far reported is too small for statistical study, yet one is irresistibly impressed with the favorable results in the cases in which sutures were not applied So that Dr Glantenay's arguments are in a measure, actually confuted by his own statistics

[2] JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION The Surgery of the Ureters, Dec 16, 1893, et seq

The rare longitudinal wounds of the aseptic ureter occurring in the course of transperitoneal operations must be disposed of by suture, if possible But if the duct is not readily accessible for this purpose, drainage through a posterior incision may be required

Certainly we have much to learn on the subject of longitudinal wounds of the ureter but our knowledge can now be advanced by clinical experience alone Meantime we should be careful to properly estimate the value of the materials already at hand

Dr Konrad Buedinger[3] has recently discussed complete transverse injuries of the ureter, detailing the methods of Poggi and of the present writer for the reunion of the duct after such traumatisms Dr Buedinger tried the method of Poggi upon a dog This method, it will be remembered, consists in the end-in-end invagination of the upper ureteral fragment into the lower To do this by means of a traction suture was found so difficult that he gave up the effort For, in the first place, the invagination would not succeed, since the upper end always slipped out of the lower end as soon as peristaltic action occurred, and, in the second place, the ureter was stretched too much transversely Becoming discouraged with Poggi's method, Buedinger gave up experiments in this line If he had tried the writer's method by lateral implantation of the upper end of the ureter into a slit in the lower portion of the tube, these objections would have disappeared

Glantenay describes the writer's method so fully and clearly that he evidently understands it, but at last discards the procedure utterly, evidently influenced by the paper of Buedinger, since he mentions no experience of his own His sole objection to the method lies in the fear that the invagination suture (by which the upper end of the ureter is drawn into the slit in the side of the lower portion) may be left in the ureter and may form a nidus for the formation of a concretion This theoretical objection is wholly refuted by the fact that this suture does not need to pass through the mucosa of the upper fragment, the muscular and connective tissue layers of the duct being thick and strong enough to give substantial hold for the thread It must also be remembered that the catgut suture would at first be likely to bury itself by cutting deeper and deeper into the walls of the ureter, and later on would be absorbed completely

Glantenay coolly states that the case operated upon by the writer's method by Dr H A Kelly, "does not seem rigorously demonstrative If it proves the harmlessness of the maneuvers which this complex procedure necessitates, its efficacy is not evident to us, for where is the proof of the reëstablishment of the course of the urine by the injured ureter?"

The child-like naivéte of this inquiry almost disarms one Yet perhaps we should take him seriously, especially as he complains that he could not find the detailed report of the case, a statement which would seem to imply that he did not have access to the *Index Medicus* and the *Annals of Surgery* even in Paris The proof which he desires lies in the following facts 1, no urine escaped through the abdominal drain leading down to the site of injury, 2, no accumulation of urine in the peritoneum or symptoms of resorption were noted, 3, a normal quantity of urine was passed and no symptoms of ureteral obstruction occurred

It may be added that Dr Doherty of Georgia, has sent the writer a very brief account of a similar case, in which he accidentally cut the ureter across during a laparotomy and immediately closed the injured duct by the same method His patient recovered without an untoward symptom

THE INFILTRATION METHOD OF ANESTHESIA IN OPHTHALMIC PRACTICE

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7 10 1895

BY H V WÜRDEMANN, M D

Director and Secretary Wisconsin General Hospital Association Oculist and Aurist to the Children s Hospital the Milwaukee County Hospital for Chronic Insane, and to the Elms Hospital Instructor in Eye Ear and Throat Elms Hospital Secretary Section on Ophthalmology American Medical Association
MILWAUKEE, WIS

Just six months ago we brought to the notice of the medical profession our[1] conclusions obtained by following out the line of experiments instituted but a few months before by Schleich,[2] of Berlin, relative to the anesthetic properties of water, and its application in surgical practice The experimental stage has been passed and we are now able to substantiate some of his statements made in our first article which at that time were not yet proved

A brief resumé of Schleich's experiments may be advisable this investigator was employed in research for the production of a better and less harmful method of local anesthesia than that which has hitherto obtained He first experimented with hypodermatic injections of cocain and other drugs, finding that a 2 per cent solution of cocain was the weakest which would produce anesthesia when introduced beneath the skin A couple of syringefuls of this solution would be the toxic dose and such an amount would be necessary in many trivial operations It is well known that cocain injection is dangerous to life and even small quantities of the drug may give rise to very unpleasant symptoms

Our investigator discovered that by injecting the solution into but not under the skin in the surprisingly small quantity of 002 to 1 00 a practical anesthesia would result throughout the whole thickness of the skin and insensibility more profound than that by hypodermatic injection of a solution one hundred times this strength could be obtained The logical deduction followed that the drug itself could not be the main agent in causing the anesthesia Injections of distilled water were tried and produced anesthesia but these were painful, *i e* the infiltration of the water into the skin produced a burning pain which transcended that of the knife Complete anesthesia however, followed the infiltration

Could it be the infiltration alone that produced the pain of injection and later obtunded the sensibility " Injections of the normal salt solution (6 per cent) were made but no anesthesia followed, yet the injection itself was painless The proposition to be solved then was as follows if infiltration of water alone into the tissues produced pain followed by complete anesthesia while the injection of 6 per cent sodium chlorid was painless but made no alteration in the sensibility of the nerve ends there must be between these two extremes a salt solution of a certain strength which would at the same time be so similar to the normal fluid of the blood as to cause little or no pain in infiltration and yet be sufficiently like water to produce anesthesia of the parts so injected Experiments proved that a 2 per cent salt solution met these requirements Solutions above or below these strengths were either painful to inject or produced no anesthesia Operations may be painlessly done by a 2 per cent salt solution I have personally experimented with various fluids the ethers and alcohols are similar to water in that they cause burning pain on injection, followed later by anesthesia Ether however, produces capillary hemorrhage and alcohol coagulates the albumin of the tissues and both substances, aside from this, are too irritative to be of use in this method The various oils are not painful to inject but afford no anesthesia They are usually absorbed without producing material change in the tissues

---

[1] Explanation and Demonstration of the Infiltration Method of Anesthesia. JOURNAL AMERICAN MEDICAL ASSOCIATION, Dec [illegible]

[2] Schleich, Schmerlose Operationen Berlin [illegible]

Cocain 2 per cent , morphin 2 per cent , ac carbol 2 per cent , bromid of potassium 3 per cent , methyl violet 1 per cent , caffein 2 per cent , sugar 3 per cent and other substances in aqueous solution were found to allow of the anesthetic action of water upon the nerve filaments The anesthetic drugs, cocain, ac carbol and morphin have a special characteristic i e , their addition in very small quantities to the 2 per cent salt solution prevented the paresthesia incident to injection of simple saline solution and the infiltration of inflamed or hyperesthetic areas could be made without pain

The narcotics were more active when used in the 2 per cent salt solution and could be used in even lower attenuations, for instance, 01 per cent cocain in a 2 per cent salt solution prevented paresthesia It was also found that if the solutions were used cold, their efficacy was increased many fold, and that when used at the temperature of the body, little or no anesthesia followed

The following formulas are advocated by Schleich [3]

R	Cocain mur	20
	Morph mur	025
	Natr chlor	20
	Aqu dest ad	100

M Sterilisat adde sol ac carbol 5 per cent gtt ij
S Solution No 1, strong For operation upon highly inflamed or hyperesthetic areas

R	Cocain mur	10
	Morph mur	025
	Natr chlor	20
	Aqu dest ad	100

M Sterilisat adde ac carbol 5 per cent gtt ij
S Solution No 2, medium For most operations

R	Cocain mur	01
	Morph mur	005
	Natr chlor	20
	Aqu dest ad	100

M Sterilisat adde sol ac carbol 5 per cent gtt ij
S Solution No 3, weak For superficial operations upon nearly normal tissues

At my request, Parke, Davis & Co , of Detroit, Mich , have prepared tablets, triturates and compressed tablets from which these solutions may be extemporaneously made by dissolving one tablet in 100 cubic centimeters (ʒiij) of distilled or boiled water These will be found convenient in practice

All are to be kept strictly sterile, glass stoppers or scorched cotton such as are used in bacteriologic experiments for the bottles, small quantities to be poured out in smaller vessels for each operation Just before operation the solution should be cooled by laying the bottle containing it on ice The common form of hypodermatic syringe with the finest of needles is all that is usually needed Dr Chas Denison of Denver, Colo , has given us an aseptible syringe of larger capacity, with piston packing of asbestos which is particularly applicable for aseptic injection The syringe is kept in good order by being frequently soaked in a 5 per cent carbolic solution and the needle sterilized after each operation

The discovery of these truths so valuable for the question of local anesthesia is due simply to a slight change of method, the application of the solution within and not under the skin The anesthesia is caused by the replacement of the normal fluids of the tissues by a fluid of less specific gravity (the water) which causes anemia, compression and cooling, producing thereby a temporary paralysis of the nerve filaments The pain of the infiltration of indifferent solutions is abolished by the minute doses of narcotic drugs, (morph cocain, carb ac)

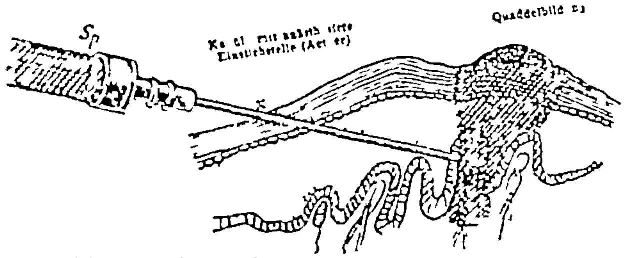

FIG 1 —Diagram of a section of the skin, showing formation of the first wheal

It is perhaps well to here go into the technique of the production of local anesthesia by this method The field of operation is made aseptic in the usual manner Having the required formula, the solution aseptic and cold, we fill the sterilized hypodermic syringe, pinching the skin slightly between the thumb and forefinger of the left hand , the needle is then passed obliquely under the epidermis to the papillæ, intra-cutaneously, until the lumen is fully inserted A few drops are then injected, thereby producing a white elevated wheal, the infiltration extending throughout the whole thickness of the skin (See Fig 1) There is immediate and complete anesthesia throughout the extent of the infiltration which lasts from ten to twenty minutes according to the density of the tissue so edematized The needle is then reinserted at the periphery of the wheal and the area infiltrated to the required extent and depth No tissue offers any deviation from the dictum every structure is made anesthetic that can be artificially edematized , this holds good for skin, mucous and synovial membrane, periosteum, fascia, muscle, lymph glands, nerves, viscera, and even bone

Anesthesia exists only within the area infiltrated by the solution and outside of that, normal sensation remains In operations or or through the skin and mucous membranes the first wheal is increased to the size of a dime by increased pressure on the piston , the needle is moved and re-inserted at the periphery of the wheal, but still within it, and a new wheal raised In this way the line of incision is marked out to any desired length or breadth (See Fig 2) In general surgical operations we would then infiltrate the underlying tissues, by slowly pushing in the needle and injecting a few drops at a time until the deeper tissue is edematized

---

[3] The "keeping" qualities of these solutions are improved by the addition of a few drops (gtt jjl) of a 5 per cent solution of trikresol as recommended by Parke, Davis & Co

By cooling the spot selected for the formation of the first wheal by ether or rhigolene spray, or on mucous membranes by touching the spot with a strong solution of carbolic acid or applying cocain, the first injection may be made, if so desired, without even feeling the prick of the needle This is seldom necessary as a very fine needle may be inserted without pain even in very tender tissues such as the eyelids The succeeding injections may now be made without causing sensation There is no sensation to the infiltration proper

Where the tissues are inflamed the sensibility is pathologically increased Here it is indispensable that the infiltration be begun in sound tissue and carried over into the part to be operated upon (See Figs 3-4) The dilated blood and lymph channels of the inflamed skin allow us to anesthetize quite a large spot from one puncture

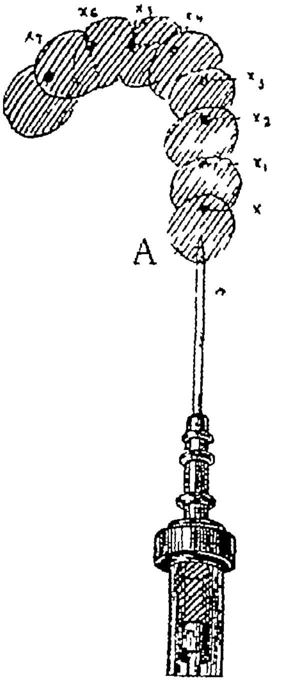

FIG 2.—Formation of the cutaneous wheals A, spot made anesthetic by ether spray for the first injection

The injection should be done slowly at first and when the infiltration - only felt by its tension we may rapidly flood the part to the required extent Under no circumstances must fluid be primarily injected into an abscess, an exudation or a pathologic focus The only result is increased tension and pain We must not lose sight of the cardinal fact that the anesthesia exists only within the area infiltrated by these solutions and that outside of that there is normal sensation The method rests principally on the production of a complete artificial edema of the tissues Wherever we wish to operate with exact anesthesia, the field of operation must be tensely filled with the solution so that it exudes from the cut surface

It should be remembered that our use of attenuated solutions of the narcotic drugs has nothing akin to the doctrine of the followers of the dogma "*similia similibus*," etc These statements may be readily substantiated upon your own persons, as I have done many times on myself and other physicians I need not call to your attention the well known dangers of chloroform and ether anesthesia and the waste of the surgeon's time, the discomfort to the patient, and the necessity for skilled assistance Cocain injection of the solutions of the usual strengths (5 to 10 per cent) is certainly far more dangerous to life than the administration of chloroform The higher solutions of cocain surely diminish the exudative process and retard the healing and, in some cases, actually destroy the trophic filaments so that gangrene has been known to occur Nothing of the sort has been found to result from the infiltration of the solutions recommended in this article Anesthesia is complete and occurs immediately and lasts long enough for almost any external operation There is no objection at any time to repeating the injection if feeling should return during the operation Indeed, we might safely operate for hours upon a small area if so inclined The advantages of the method are also evident from its simplicity, safeness and celerity

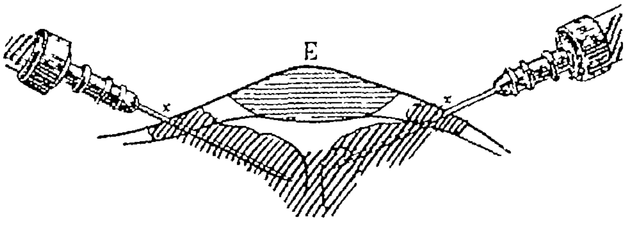

FIG 3 —Infiltration of inflamed surfaces

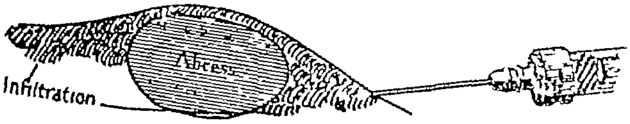

FIG 4 —Infiltration of abscess

The method has gained credence and is now in common use by many busy practitioners Operations have been done, from the removal of ovarian tumors and amputations down to the opening of boils without pain, and with satisfaction both to the physician and patient I have personally done half a hundred operations upon the eyelids, etc , by this form of anesthesia, as well as various operations upon other parts of the body while prosecuting the investigation My first operation was done upon a deep seated felon I have assisted at a number of circumcisions, excisions of tumors, and minor operations, making the injections myself, I have had reports from many surgeons in different portions of the United States of its use for operations varying in severity from ingrowing toe-nail to hernia, in which the anesthesia has been satisfactory Healing has been by first intention and in only three instances have we had reports in which it has been delayed [4]

In the foregoing, I have purposely said little about its use in ophthalmic practice, leaving this to be inferred from what I have said concerning minor surgical procedures in other localities Indeed, infiltration anesthesia is of greater value to the general practitioner and surgeon than to the oculist, as the instillation of cocain into the eye is sufficient for most of our operations. For obvious reasons this method is applicable only to operations in our practice upon the eyelids, etc. The resultant edema would interfere with most operations within the orbit such as enucleation.

---

[4] In one of the cases an operation for removal of tumor in axilla the patient used the arm freely after the operation In the other two the patients were scrofulous and healing would have probably followed the same course if a general anesthesia had been given

However, I bring the subject to workers in ophthalmic surgery, believing it will be an advantage to the ophthalmic surgeon for most operations in which instillation of cocain is inapplicable, but which may be deemed too trivial for a general anesthetic and yet are attended with considerable pain. In my practice it is in daily use for chalazia, tarsal tumors, opening of abscesses and plastic operations. For most office operations the Schleich method is an invaluable contribution to our therapeutics. It should do away with the injection of dangerous solutions of cocain and take the place of general anesthesia for many operations.

The technique of the injection was then shown upon the arm of one of the ophthalmologists there present after which by the kindness of Dr. Harry Friedenwald, of Baltimore, a patient was shown with two sebaceous cysts of the forehead. Dr. Würdemann injected the skin covering of this tumor with solution No. 1 and the growths were dissected out by a surgeon without the patient experiencing the slightest pain or feeling either the injection or the operation. Six stitches had to be taken in the wound of the larger, and two in that of the smaller growth.

[illegible] Grand Avenue.

REPORT OF COMMITTEE ON EXAMINATION AND CARE OF EYES DURING SCHOOL LIFE—INSTRUCTION OF TEACHERS AND SCHOOL AUTHORITIES AND LEGAL PROVISIONS.

Read in the Section on Ophthalmology at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY B. ALEX RANDALL, CHAIRMAN,

PHILADELPHIA, PA.

Mr. Chairman and Gentlemen:—Your Committee in approaching the subject assigned to them find themselves of one mind in advocating advance in this important field of preventive medicine, but can less easily concur upon the exact lines within which they deem it practicable to advise action at the present time. Located in cities of various sizes and widely separated portions of the country, the environment of each member must react distinctly upon his view of what it is judicious to attempt, for it is practically self-evident that the popular mind is but little prepared for any active steps in the matter, and that it will be very unwise to take a position too advanced to secure the indorsement of reasonable men, medical and lay. Public opinion alone can carry this project through, and even in the profession—nay, even among our ophthalmic colleagues—this opinion has still largely to be shaped. Our steps must be guarded, therefore, yet they need not be timid nor indecisive. We must form the advance guard, sure that the rank and file will lag behind the standard which we place before them, however wisely chosen. Let us look, then, not for our idea of the maximum now everywhere practicable, but rather for the minimum that can be held efficient and satisfactory.

The opposition likely to be encountered in our efforts to advance the cause will come primarily, perhaps, from professional jealousy rather than from school inertia or individual restiveness and assertion of freedom. That too many men intrusted with such investigations may try to coin profit to themselves from them, must be conceded; yet we contend that still more men of the first rank will refuse, or will hesitate to accept, such a trust because of the unworthy motives likely to be gratuitously imputed to them. In our noble profession there are hundreds capable and willing to take up this or any other self-sacrificing task with no thought of personal exploitation—finding their sole rewards in the knowledge thus gained and the beneficent work accomplished. There may be exceptions among those who have already wrought in this field, but we know of none. Yet any one of us in offering to do such work in his own community gratuitously, much more if claiming compensation, would be very careful to whom he broached his proposition, knowing how probably he would be misconstrued.

Let us deal frankly and fairly with this matter, individually leaving its execution wholly alone, if we have not the interest or can not afford to undertake it without more compensation than is likely to be given—and leave others unhampered by any insinuation of baser motives in being willing to carry forward the needed work.

The next line of obstruction is to be found in the school authorities. The cramming process now in vogue demands more time than can be found, so they will grudge every minute that is given to medical examinations. Ill-paid as are most of our teachers, they will at times demur to taking more work on their shoulders, or that any of the scanty school funds should be diverted to paying medical examiners. School discipline is apt to suffer in being broken in upon by such investigations; and some will fear, like the parents, lest we "put notions in the children's heads." An officially constituted group of "lame ducks" for whom forward seats, special illumination or lightened burdens would be required, is an incubus from which some would gladly escape.

Yet it is but just to another noble and valuable class in our midst to insist that the great majority of teachers will cheerfully, if not enthusiastically, hail the promise of better ocular hygiene for their pupils and make any reasonable sacrifice to do or to permit the good work. As a body they will welcome any system which will enable them to do all they can to obviate or relieve danger to their little charges. This spirit should be fostered, and they should be given test cards and taught how to use them and make other examinations within their scope; for much—all that is possible for some localities perhaps—can be thus done through the agency of the teachers.

The scholars and their elders will occasionally offer opposition, regarding such examinations as invasious of their liberties. This will rarely occur unless provoked by some indiscretion or arbitrary order of the examiner or school authorities. Yet it can be avoided only by the most scrupulous bearing on the part of the investigator, not only in setting such a study on foot, but even when it is apparently progressing most favorably. An unwilling pupil may be gently ridiculed and passed over until in better frame of mind; any coercion is likely to prove disastrous in these delicate positions. The examiner should even be very cautious as to any leading questions and very chary of remarks as to his findings, generally declining to report in any but the official form. This had better be in a concise untechnical statement to the school authorities of the vision of each eye, the character of any refraction error and, in the needful cases, that medical aid should be promptly sought, leaving them to transmit it to the parents Unless officially charged with such a duty, the examiner will be wise to refrain from all prescribing

When an examination has been authorized, how, where, and by whom shall it be made? We may look forward with hope to a time, not probably in this century, when the new pupils will present themselves for examination, physical as well as mental, before the school opens in which they desire to be enrolled For the present, we will do well if we secure the investigation of those accepted and beginning their school work For the examination of these, suitable accommodations at the school itself should be perfectly practicable, and with the needful appliances duly arranged, the study can there be made with the minimum cost of time to examiner and scholar

Many of the medical examinations thus far made could have been as well, if not better done, by an intelligent layman Little practice is needed to fit one to measure the acuity of vision The prime requisite in this and other tests, is the conscientious carrying out of the routine, and in this medical examiners may be as faulty as laymen So too as to the choice of astigmatic lines, the testing of the color sense and even taking the range of accommodation Pennsylvania railroad clerks do this very efficiently under the system devised by Dr Thomson Tests of the refraction with spherical glasses and of the muscles with prisms are rather beyond most laymen as indeed beyond most non expert physicians Ophthalmoscopy and ophthalmometry demand the highest skill of the oculist

What then shall we attempt? Shall we test vision at four feet and seek H with a + 1 lens and then set down as emmetropic and normal, all not thus proved ametropic? Such a piece of work by one ranking as an authority, is probably more quoted than any other study yet made As well record as all-sufficient, *statements of the pupils themselves!* Thus much the teachers will probably do more patiently than a physician

Every simple means of learning the real and important conditions of the eyes should be utilized since no single examination can possibly be infallible, and we might easily fail to learn the most fundamental facts if we slur our work at all A study as complete as we give to a puzzling case in private is none too elaborate, for we ought to test the color-sense as well as the vision for far and near, the muscle relations and the accommodation, and determine the refraction and eye ground conditions Field-taking can generally be omitted, and, although well used in some of these studies, ophthalmometric measurement of the cornea may be more scientific than practical

Possession of normal visual sharpness does not at all assure present comfortable use nor future safety, any more than defect of distant vision proves myopia We must know as accurately as possible what is the refraction, and test the power of the external muscles and of the accommodation, in order to know how the vision is attained and what are its chances of being maintained Nor will this suffice, for health of the intra ocular tunics is essential for good function, and we waste one of our best means of forestalling danger if we ignore the ophthalmoscopic showing as to the eye-ground Probably we can do no better than follow the scheme used by Risley in the Philadelphia schools fifteen years ago, slightly modified by Randall and employed in his work at the University of Pennsylvania and in the William Penn Charter School, as reported to this Section in 1892 Part of the work can be done by assistants, who need not be medical, just as the employes of the railroad are examined by clerks in the superintendent's office under Dr Thomson's plan, the methods and results being under the control of the examiner-in-chief, who can largely confine his labors to the strictly expert procedures Making and recording all the steps himself, the ophthalmologist can easily study from a dozen to twenty scholars in an hour—and division of labor can double the number Hence two hours a day for a month or two, would suffice for the examination of a thousand pupils, at only such cost of time and effort as most of us habitually give to our clinics

While few of us may feel moved to inaugurate such studies, in which we should be unhonored laborers and the targets of unfriendly criticism, many would feel in duty bound to consider, and probably accede to, a request from the constituted authorities to undertake such work, even though no honorarium were attached Many a study has been thus made in the interest of ocular hygiene, and we must look to this as a needful course in many instances in the future, before this matter is placed upon its proper footing There is evident limit, however, to the possibility and desirability of this, and equity demands that compensation, in small amount at least, should be offered in acknowledgment of the service This can not often be made more than a mere honorarium, which may induce the best men to accept the duty and thus exclude the unscrupulous, who would try to profit illegitimately by these appointments One hundred dollars for each thousand examinations made, should be well within the financial possibilities of the school authorities and yet a fee not unworthy of acceptance for a month or two of public work It would bring an expense of $12,000 to $15,000 to Philadelphia annually, but that is little more than Boston is now paying for medical inspection of her schools, merely to guard against infectious diseases, with such a study as we have outlined only in the dim background of the future Like the vaccine physician and other sanitary workers, the school physician must expect but nominal remuneration, especially while trying to convince the public of his disinterested motives in advocating examinations of the eyes in the schools

The details of the examination should be recorded on forms spaced for record of the date, school and class, the name, age and sex of the pupil, the report as to the general health as well as that of the eyes, with note of objective evidences of inflammation of lids, conjunctiva, cornea or tear-passages, squint, photophobia, etc , the visual acuity (stating test and illumination, when unusual), and choice of astigmatic lines at a distance and the near point of accommodation (with far point when limited), the muscle balance by Maddox rod for distance and Graefe test or pen point for near, the color sense by Holmgren's worsteds for each eye, the refraction by retinoscopy and direct ophthalmoscopy, with note of the eye-ground conditions, elaborated perhaps by lens tests with sphericals in fixed series for retinoscopy and manifest measurements. To this we should add mensuration of length of leg, thigh, back and elbow height in relation to proper seating.

THE IMPORTANCE OF MINOR CHOROIDITIC CHANGES, ESPECIALLY CONUS

Read in the Section on Ophthalmology, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY B. ALEX RANDALL, M.D.

PHILADELPHIA, PA.

Among the hundreds of thousands of eyes that have been examined more or less carefully in the schools as to their refraction, but a few thousand have been even looked at with the ophthalmoscope, and only a few hundred studied with reference to the pathologic changes in the eye grounds. Search for the causative factors in the production and increase of axial distension has led to great elaboration of many phases of the subject, yet this really fundamental one has been commonly neglected. Loring and Derby, Kopps, Scheiding and a few other investigators have recorded the frequency of conus, and Paulsen has also noted its direction in seafaring men, to learn if their frequent upward gaze made them specially prone to conus downward. But few have studied, like Risley and myself, the general normal or unhealthy condition of the fundus in its bearing upon changes of the refraction in actual progress.

This matter in its relation to general ophthalmic practice as well as in school examinations, is worthy of far better attention. In the routine recording of almost every case, the condition of the nerve margins the macula and the general eye ground should receive careful scrutiny and record. I have heard this laborious detail on the part of some Philadelphia men strongly criticised as superfluous by men trained in the best foreign clinics and returning to instruct their countrymen. If Hirschberg, Landolt, Fuchs, Nettleship and others do this only in exceptional cases, why should we do otherwise? Another question may serve as answer. When the ophthalmic world regards myopia as a condition commonly, nay usually, progressive, why are progressive cases rare in the practice of these over-minute Americans?

That the macular region should habitually be closely studied, few will question, although some of the journal articles about it seem akin to old ophthalmoscopic hand-book statements that "some observers *claim* to have seen the macula in life."

The facility, if not indeed the practicability of such study is less to those who make little use of mydriatics or who accept failure in such scrutiny before they have even attempted it. Those who practice it whenever at all possible, will be well rewarded. Not only will many cases of renal disease be thus detected long before the usual symptoms have attracted attention, but many peculiar minor lesions will be noted, of which the meaning is not yet so clearly understood. Yet lesions in this region of supreme importance can not be too *early or* carefully investigated. Hirschberg asserted not long since that the *majority* of senile eyes showed gross alterations at the posterior pole in a way that suggested that he had not long been as familiar as he should have been with these lesions, nor examined enough eyes carefully to have learned how many are totally free from them.

As to the "conus" and crescent formation at the nerve margin, much as has been done and written for its elucidation, there is great need for farther and better study. Little advance has been made since von Jaeger's investigations a quarter century ago, although many a backward step has been taken, which has complicated the matter for later students. Some deny, like Stilling, that there is an inflammatory element in its causation, regarding the white crescent more or less exposed, as a glimpse into the distended nerve sheath. Yet daily observation teaches us that this is rarely true, and that the common changes at the nerve margin have no *certain* relation to the distended nerve sheath and other gross posterior alterations. We have most of us seen these crescents appear as orange-red areas where there was little pigment-heaping to obscure the process, and, perhaps have seen them disappear with quite the same rapidity. Those who have failed to make verbal or pictorial note of this, have doubtless distrusted their observations, for hardly any one has written about it. More often the change has been in the absorption of the pigment ring, both at the outer and inner margin, and this becomes broken, gray, double-ridged, then semi-atrophic and before the cycle is completed by its full atrophy and uncovering of the sclera, the process is being repeated in one or more crescents beyond the first. Three and sometimes four of these crescents will be seen in one eye, revealing at one glance the steps of the change, the outermost being fairly recent and perhaps still amenable, like any other choroiditic patch, to treatment by mydriatic rest and alteratives. That they are generally of inflammatory nature can be doubted by few close observers, too often they have passed unstudied if not noted, and their significance has been lost sight of. At the inner margin, the double ridged gray crescent is regarded by Nagel as a *supra-traction* of the choroid, such as v. Jaeger described and drew in his "*Einstellungen*," and Weiss has demonstrated in myopic eyes. This is quite clearly the case in a few instances, and the curvilinear nasal reflex of Weiss, to which I have several times called attention, is present to show the distorted prominence of the locality. Yet any one who will sketch a few thousand eye grounds will find his portfolio, like mine, more stocked with exceptions than instances of most these ill grounded *theories*.

Transparent as is the normal retina, its fibers are usually visible to close study along the larger vessels above and below the disk, while weak illumination will make still other of its structures apparent around the margin. The increase of this opacity is very marked in some cases of retinitis, but short of this, we may have many undefined grades of haze which belong, like the exaggerated striation, to conditions better termed irritative than inflammatory. This phrase should not imply that they are not due to true low-grade inflammation. It marks in the usage of some men, that they have little tendency to progress into the serious infiltrated and extravasating lesions which we commonly associate with the name retinitis. Usually accompanying the minor retinal alterations are parallel changes in the choroid, due to little more perhaps than hyperemia, yet generally quite recognizable The delicate stipple of the retinal pigment layer is lost in the flushed appearance that Risley has well likened to canton flannel Let this long persist unrelieved, and absorption will become evident, which lays bare the larger choroidal vessels and heaps the pigment in their interspaces Most juvenile eyes, even in brunettes, show in the periphery some uncovering of the choroidal circulation, and in blondes this almost attains the albino type But it is quite another thing to find visibility of the vessels of the choroid near the disk, and clouds of pigment heaping in the stroma between them, mark the pathologic nature of the process There should be as little question as to the meaning of the picture, in these commonly ignored cases, as in those where it forms part of most serious processes

The apparent vascularity of the nerve-head has wide variations within normal limits, depending largely upon the size and depth of the central excavation, the visibility of the scleral ring, the size of the pupil and even the refraction One can at times see his own optic disk flush under the irritation of prolonged autophthalmoscopy, and realize that similar fleeting variations are often presented to his study With any persistent hyperemia there is apt to be a visible distension of the lymph sheaths surrounding the retinal vessels and pulsation, often very striking, in the large retinal veins No single feature of this may be beyond possibly physiologic limits, yet the complex is one that should be unmistakable to the careful ophthalmoscopist Slight tortuosity of the smaller vessels may be indistinguishable from their normal sinuous course, but this aberration can not seldom be actually followed through every stage up to that of marked neuro retinitis, in cases where eye strain from refraction error seems the only assignable cause The configuration of the disk, with the form of its *porus* and the trend of the vessels on and near it and the other features of what Thomson has termed "drag," also deserve distinct note, as furnishing evidence that the tissues near the pole are actually undergoing the plastic changes for which the hyperemic softening has prepared them

Minute observation and note of the conditions of margins and excavation of the nerve, the trend of the vessels, the absorption of the choroid ring and the general hyperemia and pigment disturbance of the eye-ground, repeated at intervals, will generally demonstrate progressive changes about the posterior pole and serve to explain why the patient suffers so much asthenopia in the process Sketches, however rude, can give accurate portrayal of the proportions of disk, vessels, *porus*, crescent, etc , and serve better than any verbal note to make evident the changes from time to time And this not only in eyes progressively myopic or other cases of changing refraction, but in a few where the hypermetropic refraction remains unaltered And in the cases of progressive myopia, a group to which Risley has called attention, will be brought more clearly forward, in which no alterations appear at the posterior pole to indicate staphyloma there, while the marked choroiditic disturbances at the equator mark this as the site of the stretching which is lengthening the optic axis

1806 Chestnut Street

A STUDY OF THE REFRACTION OF SEVENTEEN HUNDRED EYES

Read in the Section on Ophthalmology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7 10 1895

BY H BERT ELLIS, M D
LOS ANGELES, CAL

The question of refraction is one that plays no unimportant part in the daily work of many oculists in our large cities, and of most oculists in our medium and smaller cities With many it forms the great bulk of their work

I present for your consideration to day in tabular form, a study of the refraction of 1,700 eyes, representing 869 patients taken from the last 1,000 consecutive eye cases coming under the care of the writer in his private practice Of the 131 cases not incorporated in this study, some were infants with various inflammatory troubles and some operative cases, five only being presbyopes with emmetropic eyes Thus you will see that about 87 per cent of all my eye cases required correction of ametropia Dr Geo M Gould in a paper on these very lines, read before this Section in 1891 said that 93 per cent of his eye patients required correction of errors of refraction If, therefore, from 85 to 95 per cent of all eyes that come under the oculist's care need errors of refraction corrected, it will be wise for all of us to give the subject some little consideration

Of the 869 patients whose eyes form the basis of this study, 613, 70 per cent, were females, and 256, about 30 per cent, males, a proportion of nearly 2 5 to 1 The same general laws underlie this disproportion between the sexes in ophthalmologic practice that cause a similar disproportion of males and females in other branches of medical work, *e g*, among the women we find less general vigor, less active life, with closer confinement, more constant and finer work in the application of the eyes, and last but not least a more sensitive and high strung nervous mechanism

Although 19 per cent of the patients were presbyopic, no account is taken of the presbyopia in these tables In 66 per cent of the patients under 40, a mydriatic was used, ordinarily I employed ophthalmic disks composed of homatropin and cocain, of each 1-50 gr, to produce mydriasis Where the use of three or four of these disks in each eye within a period of one and a half hours failed to quiet accommodation, I used a few drops of an atropin solution, 4 grs to the ounce, in each eye four times daily for three days I have, however, had but few cases in which I have had to resort to this method I have left out of this study all aphakic eyes, and all eyes in which disease of the refracting media or fundus had impaired refraction In the preparation of my tables I followed the same general plan adopted by Dr Gould in his paper of four years ago

I have in Table 1 given the general refraction of 1,700 eyes, 1,371, or a little over 80 per cent, were hyperopic, 282, 16 59 per cent, myopic, while 17 were myopic in one diameter and hyperopic in the other Of my hyperopic cases, I found only 16 per cent with simple hyperopia, 84 per cent had astigmatism simple or compound, the simple astigmatism amounting to 37 per cent of all the hypermetropia Among the myopic patients we find very nearly the same proportion, 17 per cent of simple myopia "2 per cent of simple myopic astigmatism and 51 per cent of myopia with myopic astigmatism

Table 2 gives the amount of hyperopic correction in 867 eyes but does not include the astigmatism It will be noted that 12 per cent of the eyes had hyperopia of 0 50 D or less and 31 per cent had less than 1 75 D The eyes having hyperopia combined with astigmatism outnumbered the simple hyperopic eyes more than 3 to 1 Although the table shows so large a number of eyes with small hyperopic errors, it must not be supposed the total error was correspondingly small because with small amounts of hyperopia, I frequently found large amounts of astigmatism

Myopia is classified in Table 3 In comparison with the hyperopic table, we find only 31 per cent of the eyes have errors of 0 50 D or less, against 12 per cent of the hyperopic eyes, and 62 per cent against 81 per cent with errors less than 1 75 D On the other hand, it will be seen that over 21 per cent of the myopic eyes have between 5 50 D and 22 D of error, while less than 2 per cent of the hypermetropic eyes had corresponding errors

Of the 1,700 eyes whose refraction was measured, 1,434 were astigmatic, but in 47 of these the astigmatism was mixed, and I have consequently given them a table by themselves The varying amounts of astigmatism in the remaining 1,387 eyes is given in Table 4, 1,158 of the eyes, 83 per cent, had hypermetropic astigmatism In 72 per cent of all the astigmatic eyes the error was less than 0 75 D, while 92 per cent of the eyes had errors less than 1 75 D 193 of the eyes had only 0 25 D of astigmatism and yet I found it both wise and expedient to correct the greater number of these small errors As we would naturally expect, we find relatively a large number of small degrees of hyperopic astigmatism, and proportionately large errors of myopic astigmatism, for instance, 20 per cent of the myopic astigmatic eyes had errors above 2 D, while only 3 per cent of the hyperopic astigmatic eyes had correspondingly large errors

The axes of the 1,434 astigmatic eyes are classified in Table 5 I have used the term unsymmetrical, in a somewhat narrow sense and not with its usual significance In Table 5, unsymmetrical simply means the departure of the axis of any given eye from 90 or 180° without reference to the axis of its fellow, excepting where the axes of the pair is symmetrical Under axis 90°, I have included every eye having its axis so placed, irrespective of the fact of the fellow eye having no astigmatism, or the axis at 180° or some oblique angle, and, similarly, all axes at 180° are placed together, 55 per cent of all astigmatic eyes had their axes at 90°, while 25 per cent had them at 180°, leaving only 20 per cent with oblique axes Among the hyperopic astigmatic eyes, 62 per cent were according to rule at 90°, and 20 per cent contrary to rule at 180°, while in the myopic table only 51 per cent are according to rule at 180°, and 24 per cent against the rule at 90° The unsymmetrical cases were relatively more numerous among the myopes

The unsymmetrical axes or those varying from 90° and 180° are grouped in Table 7, and it will be seen that, among the hyperopic eyes, 49 per cent of the unsymmetrical eyes had their fellow eyes with astigmatism at 90°, and 12 per cent at 180°, and in the myopic division 9 per cent had fellow axes at 90°, while 21 per cent had them at 180° Of the 201 unsymmetrical eyes, 52 per cent have the axis of their fellow eye at 90° or 180° In studying the deviation of the axes from 90° and 180°, I find no definite rule, but simply a tendency of the hyperopic axes to be near 90°, and of the myopic axes to depart but little from the horizontal diameter For instance, thirty six of the hyperopic astigmatic eyes had their chief diameter at 75°, twenty-four at 105°, thirteen at 60°, and seventeen at 20° Seventy per cent of these hyperopic variations diverged within 30° of the perpendicular diameter on either side In the myopic variations, six were at 165°, seven at 150°, seven at 15°, and twelve at 30°, while 65 per cent were within 30° of the horizontal diameter, which is in accord with the ordinary teaching In Table 5, the axes of all my astigmatic cases were given, but in Table 4, the refraction of forty-seven eyes, the mixed astigmatic cases, was omitted The refraction of these forty-seven eyes, expressed in terms of crossed cylinders, is given a table by itself We have, however, no particular lesson to draw from it, or point of interest to call to your attention, excepting a fact, which the table itself does not show, and that is, that it required but weak glasses to make the correction in the greater number of these eyes

TABLE 1—GENERAL REFRACTION—1700 EYES

	Eyes	Per cent of H	Per cent, of all
Simple hyperopia	218	15 90	12 82
Simple myopic astigmatism	504	36 76	29 65
Hyperopia plus hyperopic astigmatism	649	47 31	38 18
	1,371	100 00	80 65
		Per cent of M	
Simple myopia	48	17 05	2 82
Simple myopic astigmatism	89	31 56	5 24
Myopia plus myopic astigmatism	145	51 41	8 53
	282	100 00	16 59
Mixed astigmatism	47		2 76
	1 700		100 00

TABLE 2—REFRACTION OF 867 HYPEROPIC EYES, ASTIGMATISM NOT INCLUDED

D°	H	H Ah	H H and Ah	Eyes	Per cent of H	Per cent of all
1-4	8	112	120	364	41 98	21 41
